THE NATURAL HISTORY OF RHEUMATIC CARDIAC DISEASE A STATISTICAL STUDY*

I ONSET AND DURATION OF DISEASE

ALFRED E COHN, M D

AND

CLAIRE LINGG

NEW YORK

We are approaching the end of a study which has occupied us continuously for fifteen years. The task that was set was an attempt to describe the natural history of rheumatic fever, presumably a single disease. The results have been accomplished through the cooperation of many persons of good will.¹ The brief descriptions and the generalizations now possible could not have been made without the great labor or the continued reflection which have been devoted to this task.

It is not too much to say that we know the behavior of rheumatic fever, at least in this locality and at this time. It is possible now to separate knowledge which is complete and definitive from information which is partial and tentative. It is possible, furthermore, to interpret the latter in terms of the former. The length of time during which we have been familiar with this subject has made it possible to reduce the descriptions to relatively few categories. It has been as important to us to be explicit where knowledge is full as we have known it to be desirable to be circumspect where it is partial.

This study was made in collaboration with WPA Official Project No. 65 197 WP 23 (N Y C)

This general paper was presented in outline before the Graduate Fort night of the New York Academy of Medicine Oct 23 1941

From the Hospital of the Rockefeller Institute for Medical Research and the Heart Committee of the New York Tuberculosis and Health Association Inc

Part II on the manifestations of rheumatic activity recurrence severity of infection and prognosis will appear in the next issue of THE JOURNAL

The statistical assistants on whom we rely for the collection and refinement of the original material as well as for the subsequent statistical analysis and arrangement comprise Rose Goldman Rita Goldsmith Lily Popper Eve Saper Harriet Steinhilber and Alice Whittemore. Without the devoted cooperation such as they gave us these studies could not have been made.

1 The Commonwealth Fund and the Metropolitan Life Insurance Company gave financial assistance in the early years of this investigation. The members of the Committees on Research on Clinics and on Criteria of the New York Heart Association gave technical advice and assistance. Many physicians and social service workers in the cardiac clinics recorded in detail week after week histories and physical examinations reports and abstracts of medical records were sent to us by hospital superintendents and record librarians convalescent homes social agencies and many physicians in private practice the directors of pathologic laboratories and the medical examiner's office of the health department of New York City made available copies of autopsy protocols and Dr Clarence E de la Chapelle reviewed postmortem reports the board of health of New York City made available to us death certificates the WPA provided clerical and statistical assistance and traced the whereabouts of thousands of patients no longer attending the clinics and obtained from them after histories which made it possible for us to complete the records up to the year 1938 1939 of 97 per cent of the patients both dead and living Miss Anne Spremann of the staff of the New York Heart Association ably supervised this work. The Board of Education the Department of Public Welfare numerous other social agencies the New York City branch of the U S Post Office and the Consolidated Edison Company all aided in locating patients. The patients themselves and their friends supplied us with information essential to completing the life histories in the large number of cases

These introductory remarks would be incomplete unless emphasis was placed on the environment in which this study took place. Only an organization such as the New York Heart Association, a committee of the New York Tuberculosis and Health Association, formed of men and women of professional stature equal to theirs could have supplied the thought and guidance which served first as the basis and later as a background for these labors.

When this study was undertaken directly at the end of the first great war, alarm was beginning to spread at what seemed to be a rapid increase in deaths from cardiac diseases. At first it was impossible to find explanations for this appearance. It was necessary to explore avenues and to ask questions designed to clarify the situation. On the result depended the means to be employed in the care of the public health. The kind and nature of the diseases, the degree of their communicability, the kind and age of the persons affected, the duration of the phases of each kind of disease, the duration of the diseases, the numbers of persons subject to each variety of ailment, what institutional arrangements were necessary at the various stages and what equipment was desirable for diagnosis and treatment—all these needed to be canvassed.

The first contribution that illuminated any of these vexed questions was made by Wyckoff and Lingg,^{1a} who described the distribution of cases in an adult cardiac clinic at the Bellevue Hospital in New York City. There was a thorough study of the incidence and classification of the cardiac diseases as a whole. They found that to the total rheumatic fever contributed one fourth, arteriosclerosis two fifths, syphilis one tenth, cases of unknown origin one tenth and cases of all other origins one tenth. They found also that 90 to 95 per cent of rheumatic cardiac diseases occurred before 50 years and more than half of them before 30, that half the cases of syphilis developed before 50, and that 80 to 95 per cent of cases of arteriosclerosis developed after 50 years of age. It was not difficult after their investigation to decide that cases of rheumatic origin deserved attention first. If there were no other reason for this selection, the fact of its occurring in young people and of being conceivably preventable would have been justification enough.

How the matter lay, then, is clear from this quotation.²

"No doubt we shall learn much from the changes in shape of specific death rate curves. We must study whether, if these changes have occurred they have

2 Cohn A E. Statistical Studies Bearing on Problems in the Classification of Heart Diseases. I Introduction. Am Heart J 1: 432 1926.

occurred as the result of efforts at prevention of infectious heart disease in early life or for causes related to the saving of life at other decades and from other diseases. We must learn what percentage (whether the number of cases remains stationary or increases or decreases) is prevented, what percentage cured, what percentage senescent. Only by analyses such as these shall we learn the nature of the problem with which we must deal, and on what aspect of it is the major emphasis most intelligently to be placed.

"There are many other problems for which our methods may yield solutions: studies in the natural history of these diseases, their duration, and whether this is modified, and how much, by differences in social and economic environment, does symptomatology vary with class and with age, what is the bearing of age on the possibility of recovery, what influences are exerted on their course by treatment, of what use are certain forms of treatment, such as rest, work, homes for convalescent patients, operations on portals of entry, such as teeth and tonsils."

Familiarity with the study of acute infectious illnesses has accustomed physicians to viewing processes of disease as taking place within short periods of time. The exanthemas, lobar pneumonia, typhoid, all fall into this group. The beginning, the middle and the end, together with the sequelae, fall easily within the purview of single observers. Even pulmonary tuberculosis does not fall outside this category. The situation is quite different in such other diseases as those which are the concern of these studies. They are all long drawn out and endure in rheumatic fever about thirteen years on the average, in syphilis perhaps half as long again and in the later arteriosclerotic forms, whether long or short, the onset often being difficult to define. In any case the whole of the life of persons afflicted by this group of ailments has not often been the subject of surveys by single physicians. Because of this fact episodes occurring in the course of such illnesses have attracted attention and study, rather than the processes themselves in long drawn out continuity. These have almost necessarily escaped description from the point of view of the whole of their natural history because a sufficient number of cases exhibiting such phenomena have not been investigated by properly trained and interested physicians.

Discussion of the natural history of rheumatic fever has accordingly been made difficult by the partial descriptions that have been available. The facts can be and indeed have been analyzed and presented from several more or less incompatible points of view. The view of private practitioners is necessarily limited by their personal experience. That of attending physicians of hospitals is circumscribed by the procedure of admission and discharge, often with incomplete knowledge of the subsequent history of patients. Public health officers describe the course of events naturally in terms of vital statistics.

The point of view in this study corresponds to none of these. It began and has continued to regard solely the natural history of this disease as exhibited by the continued histories of given individuals, from its onset until its end in these same individuals. This study is based accordingly not on cross sections, not on impressions, not on statistical averages but on histories literally representing courses of events. Because this was the plan, it has been possible to study aspects of the disease in their context. It is known, for example, that a certain phenomenon, if it appeared in a child, could subsequently

be observed as it evolved in the later history of that individual and so could be related causally to its presence at earlier stages. The development of rheumatic phenomena is known therefore in continuity. Truth can be discovered no doubt also by other techniques, as for example by random sampling of phenomena but, if it is a virtue, this investigation can claim knowledge derived from close observation together with the management and treatment of the very individuals whose illnesses have been analyzed. From this point of view the cases studied have the kind of value to be found in descriptions of cases reported by private practitioners.

The methods that have been employed are in essence not new, but they have been scrutinized afresh in order to fit the current uses to which they were put. To collect information of so large a number of cases it was necessary to define carefully the terms that were used. The selection of the terms was itself a matter of prime consideration. The Committee on Criteria of the New York Heart Association made these selections. It decided on and published appropriate definitions.³ This procedure eliminated vagueness and confusion. Since the number of cases to be studied was large, it was necessary to record the histories in ways that made enumeration readily possible. Charts were therefore designed in which answers were entered in accordance with properly formulated questions. The questions were so put that the answers were as nearly as possible unequivocal. The charts consisted of parts so as to provide the opportunity to enter for each patient his history, his physical examination and his subsequent course. These charts were made in duplicate, the originals being retained by the clinic in which a patient was treated, the carbon copy being brought for file and subsequent analysis to the central office.⁴

Besides criteria and methods of recording, the ends in view could not have been accomplished had not the Committee on Cardiac Clinics seen to it that suitable quarters and adequate equipment were available.⁵ In the early years physicians who attended the cardiac clinics met frequently for consultation on all the methods used. These conferences made reasonable uniformity of view and usage possible. Physicians willing to accept these methods constituted the indispensable cornerstone of the enterprise. But none of this apparatus could have sufficed had it not been for the statistical assistants provided by the New York Heart Association. It was their duty to attend clinics, to see to the upkeep of the records and more especially to the uniformity in the use of nomenclature and symbols which had been decided on, and finally to assist in completing, editing and analyzing the data.

If there is doubt of the value of results such as these, the doubt must, it seems, rest on popular conceptions of the nature of statistics. What physicians require and what after all they must have in the practice of medicine is information twofold in nature. They must know about the general movements of diseases, or their natural history, but they desire also a knowledge of methods which make applicable to individual cases the general considerations to which reference has been made. The difficulty is here. Except as far as the former aids an

⁵ Standard Requirements for a Cardiac Clinic. New York Heart Association. New York, 1936.

understanding of the latter, it can scarcely be pretended that the statistical or general method can be a useful practical instrument. Why this is so demands perhaps some discussion.

"The search for law in biology and of course in medicine rests on the conception that the discovery of laws has served the physical sciences in extraordinarily useful ways. There can be no doubt of the soundness of this belief. But precisely what the analogy is between law and the individual in the physical world, and law and the individual in the biological one, requires precise definition—more precise indeed than is usually accorded to this matter. If there is a difficulty it lies, we believe, in misunderstanding this relation of law to the individual in the physical world. The view we take may be illustrated. In the case of the gas laws for instance, beginning with Boyle, a number of statements have been made which permit accurate predictions of the behavior of volumes of gas, that these laws do not describe the behavior of individuals within the volume is amply demonstrated by reflecting on the fact that the kinetic theory assumes violently diverse and unpredictable behavior on the part of the individual molecules in these volumes. The laws apply to the mass, the volume, the average, they make no statements concerning individual performance. And yet the laws are invaluable, they and their kind are the basis of calculation in the practical as well as in the theoretical world. In biology and in medicine, just as in physics, it is not to the individual that the laws, whatever they are or may be discovered to be, apply. Individuals represent deviations from any law both in biology and in physics. Deviation is the fate of the individual, uniformity in the sense of identity either of being or of behavior scarcely exists. The general behavior of patients afflicted by typhoid fever or the general behavior of mobs may be known, but to know these phenomena has relatively speaking little meaning in understanding or in predicting the conduct of any individual in a mob or in making an accurate prognosis, based on general experience in the case of any patient suffering from typhoid fever. And yet no one denies that general statements can be made and are useful in physics and in psychology, or that general statements on prognosis and on the natural history of diseases have value. General statements and inference in individual instances each have their domain of eminent usefulness. Harm results only when the nature and objects of the two are confused. Whether in the natural history of any one of the cardiac diseases, or in an estimation of prognostic values, or in the measure of success of a therapeutic agent, or of the degree of relevance of social or economic advice, the aim of such studies as this is the attempt to understand general movement. No other indeed is possible. Because it is the plain teaching of the history of science, the Research Committee of the New York Heart Association believes that the ability to attain orientation of this sort is indispensable in envisaging the probable course of any individual life or of any individual act. Thought and action would otherwise be chaos."⁶

LITERATURE

The problem of what reference should be made to the literature of this subject has been a source of some concern. It has a large extent and very great value. Particular aspects must necessarily receive mention and comment in the text. But since these researches con-

cerned an analysis of a large body of fact assembled in a somewhat novel fashion, it seemed more important to let the facts speak for themselves than to match them with data already available. Where there is conflict in interpretation this will of course take place.

Probably the earliest statistical report on this disease is to be found in Haygarth's⁷ monograph on acute rheumatism published in England in 1805. "Among the higher and middle ranks of society," says the author, "I have noted and classed the cases of 10,549 patients from 1767 to 1801, also clinical reports of a large number of diseases among persons in the lower ranks of life, being cases of all in- and out-patients at the Chester Infirmary for thirty-one years." After eliminating cases of nodosity of the joints, tic douloureux, sciatica, lumbago and other conditions there still remained 470 cases of rheumatism. Since only 170 were febrile, these alone were included in his analysis of "acute rheumatism." In numerous tables he described the disease with regard to sex, age, seasonal incidence, latent periods, joints involved, pulse rate, urine and blood tests. This is probably the first accurate account of the natural history of polyarthritis.

Eighty-four years later, in 1889, Cheadle⁸ published his lectures delivered before the Harveian Society of London on "The Various Manifestations of the Rheumatic State as Exemplified in Childhood and Early Life," in which he analyzed tables published in 1888 by the Collective Investigation Committee of the British Medical Association. These tables were based on reports of observations on 655 cases of acute rheumatism furnished by medical practitioners of the United Kingdom from 1882 to 1886. Among the factors considered were age, sex, occupation, locality and atmosphere, previous illnesses, influence of treatment, duration of fever, pain, extent of joint disease, complications, relapses, cutaneous eruptions, subcutaneous nodules, sequelae and deaths.

When after World War I it was pointed out that the death rate from cardiac diseases seemed to be rising, certain facts began to be subjected to more searching analysis in order to learn what actually was the situation in respect to these diseases. In 1927 a study of mortality curves for a period of fifty years made clear that the fall in rate in infectious diseases was intimately related with the rise in the cardiac ones.⁹ But five years later,¹⁰ in 1933, closer scrutiny of the data led to the inference that the increase in the cardiac death rate was relatively slight and that changing fashions in diagnoses were responsible for the apparently great increase.

In the years following the war many studies of rheumatic fever and rheumatic cardiac disease began to be reported. Among the more important statistical studies are those of the London County Council,¹¹ the Medical Research Council¹² and the Ministry of Health¹³ in

England, and the recent investigations of Hedley¹⁴ of the United States Public Health Service. During the past two decades studies based on the clinical observation of series of patients, ranging in number from somewhat less than 100 to about 1,000, include in England and Wales the work of Poynton,¹⁵ Coombs,¹⁶ McSweeney,¹⁷ Findlay,¹⁸ Coates,¹⁹ Campbell and Warner,²⁰ Miller,²¹ Horder,²² Brenner,²³ Dally,²⁴ Grant,²⁵ Hill²⁶ and Schlesinger,²⁷ and in this country the work of Mackie,²⁸ White,²⁹ Wilson,³⁰ Shapiro³¹ Sutton³², Jones,³³ Kaiser,³⁴ Paul,³⁵ Davis and Weiss³⁶ Willius³⁷ Ash,³⁸ Clawson,³⁹ McLean,⁴⁰ Leonard,⁴¹ Juster,⁴²

Stroud,⁴³ Coburn,⁴⁴ Swift,⁴⁵ Tarant,⁴⁶ Boas,⁴⁷ Thayer,⁴⁸ McCulloch and Irvine-Jones⁴⁹ and preliminary studies⁵⁰ made in collaboration with the Committee on Research of the New York Heart Association.

These studies deal with various aspects of the disease, notably its prevalence, familial and seasonal incidence, age at onset, its various manifestations and cardiac implications. Unfortunately this vast amount of data cannot be successfully pooled because of a lack of uniformity in observations and definitions, because the groups of cases analyzed are themselves limited either as to age, some having been selected from pediatric services only, and others from clinics and wards specified for adults, or as to source, comprising in some instances hospital admissions, in others ambulatory patients in public or private practice and in still others cases selected from postmortem records. Unfortunately too the criteria of statistical analysis that were employed have usually not been defined. The failure to take into consideration recognized, simple statistical procedure has often resulted in contradictory and controversial conclusions.

MATERIAL FOR STUDY

This study of rheumatic cardiac disease has been conducted on the basis of records of some 12,000 patients prepared by the New York Cardiac Clinics. Of these 3,129 are dead.⁴¹ There were male and female patients

51 The patients were treated in clinics over a period of years ranging from 1923 to 1938. Of the records analyzed 30 per cent were derived from clinics in city hospitals and 70 per cent from clinics in voluntary hospitals. About 70 per cent were contributed by clinics in the borough of Manhattan thirteen for adults and twelve for children. The hospitals represented were Bellevue, Beth Israel, Fifth Avenue, Joint Diseases, New York Nursery and Childs, New York New York Infirmary for Women and Children, New York Post Graduate, New York Polyclinic, St. Mark's, Babies, Lenox Hill, as well as the Cornell Medical School and New York University Medical College cardiac clinics and clinics attached to the Bowling Green Neighborhood House and Greenwich House Settlement. In addition 15 per cent were contributed by two clinics for adults and three for children in the borough of Brooklyn, Brooklyn Jewish, Cumberland and Kings County hospitals, 8 per cent by two clinics for adults and one for children in Morrisania City and Montefiore hospitals in the Bronx, 5 per cent by a clinic for adults and one for children in St. John's Hospital, Queens, the clinic for after care conducted by Irvington House contributed records from clinics in all the boroughs of New York City. Of these 6 per cent were derived from clinics not cooperating with the New York Heart Association. Clinics in Philadelphia—in the Graduate Women's Philadelphia General Presbyterian, Lankenau, Misericordia, St. Christophers and Abington Memorial hospitals—contributed 4 per cent of the records. Altogether only 8 per cent of the patients were treated in more than one clinic.

ranging in age from early childhood throughout the span of their surviving lives. It is in the interest of simplicity to describe the course of events in rheumatic fever first as exhibited by those who have died. Completed lives such as these render unequivocally reliable the inferences which are drawn concerning them—their course and prognosis. To these results may be added those modifications which apply to the living.

When they first came under observation in the clinics, 22 per cent of the patients were less than 10 years old, 45 per cent were under 15, and 53 per cent under 20, 13 per cent were in their twenties, 16 per cent in their thirties, 12 per cent in their forties and 6 per cent 50 years or older. About half, in short, were under 20 and half over 20.

Race—The hospitals in New York City from which 94 per cent of the records came are situated in districts in which there is no large Negro population. Only 5 per cent therefore of the records analyzed were of Negroes. This study concerns itself consequently primarily with the occurrence of rheumatic fever in the white races.

Sex—The supposition is general that girls are more often afflicted than boys, but when so large an experience as this is available it appears that this is not the

It is clear (chart 1) that there is a slight difference between the sexes in the age at onset. The mean age for males is 14.5 ± 0.3 years and for females 15.0 ± 0.3 years. The difference 0.5 ± 0.136 may be considered statistically significant. The age at onset is on the average slightly higher in females than in males.

Chart 2—In the young onset of rheumatic cardiac disease is characterized by polyarthrit. in about one half and by carditis and chorea in about one third each. In adult life onset is characterized chiefly by polyarthrit. and with advancing age by appearance of valvular lesions alone.

Rheumatic fever may begin at any age, but it begins more often at about 8 years than at any other age. At 15, the mean age at onset, 70 per cent of persons afflicted have already acquired the disease.

Year of Onset—The calendar years in which these patients acquired the disease ranged from 1870 to 1938. In 7 per cent the onset occurred before 1900, in 11 per cent between 1900 and 1909, in 24 per cent between 1910 and 1919, in 45 per cent between 1920 and 1929 and in 13 per cent after 1930.

Chart 3—Rheumatic cardiac disease. Age distribution of first manifestations.

INITIAL MANIFESTATIONS

In studying the manifestations of rheumatic fever, whether in the young or in the old, the similarity between males and females is close enough so that a description of one will do for the other (chart 2). If the usual manifestations of rheumatic fever are taken to be inflammation of the joints, muscle and joint pain, chorea and carditis, and if these taken together are regarded as infectious manifestations, it is evident that

Chart 1—Rheumatic cardiac disease. Onset usually in childhood especially between the ages of 5 and 10 years, with maximum rate at age 8.

case—the two sexes are afflicted in equal numbers. There were 1,566 males and 1,563 females.

Age at Onset—The ages found in this study at which rheumatic fever begins deserves credence because on close scrutiny the records exhibit a high degree of probable correctness. In the absence of a specific diagnostic test it is often difficult to be certain of the presence of rheumatic infection. By onset is meant, therefore, the first clinical manifestation of the disease. Since many patients first came under observation in the clinics some time after the onset (one fourth within less than a year and one half within three years thereafter), in order to date it correctly, every effort was made to obtain a reliable history. Past medical records were investigated in order to try to confirm the patient's recollection and so to lessen the chances of regarding a recurrence as the initial disorder.

In most of the published reports dealing with the age at onset, the cases analyzed are grouped according to age. If the analysis is based on children's clinics, the onset cannot escape being regarded as early, if based on adult clinics, late. In this study there is no loading in favor of any age.

among those in whom the disease is acquired before the age of 10 infection is the characteristic form of onset in over 85 per cent of cases. After 40 a little more than 20 per cent exhibit this form of the disease. Before 20 muscle and joint pains and chorea account for 20 per cent of cases, but after 20 these forms tend to disappear

Chart 4—The mean duration of rheumatic cardiac disease is about thirteen years from onset to death

Instead, polyarthritis or valvular lesions alone are found. The picture becomes totally reversed. Before 10, valvular lesions alone are the first manifestation in only about 15 per cent of cases, after 40 in almost 80 per cent.

It need scarcely be pointed out that, though this is the distribution of first manifestations, numerically the group after age 40 is small and amounts to not more than 5 per cent of the total.

As initial phenomena for dating the onset of rheumatic fever the meaning of muscle and joint pains has often been called in question. How to be certain when they are significant is difficult and requires definition. In this study they are so regarded (in 281 cases or 9 per cent, table 1) only when additional evidence appeared later. It did so within one year in one third and within three years in almost half of the cases.

That acute inflammation of the joints is almost twice as common as active carditis in young persons is contrary to the general impression. An explanation for this

not an uncommon experience to discover that what impresses physicians are valvular lesions. But in the mothers and in patients it is the multiple disorders of the joints. No doubt carditis is often present as well.

Although it is clear that rheumatic fever is a disease occurring predominantly in childhood and early adolescence, and although the relative frequency of its manifestations is as has been described, the age distribution of these manifestations as first phenomena permit a somewhat more detailed analysis (chart 3). It has already been said that chorea comes practically to an end at the age of 20. In point of fact there are few cases after 15. The greatest number actually occur at about 8 years of age. Indeed, no other manifestation is so centered on a single age. Carditis takes its maxi-

TABLE 1—Type of Onset

Type of Onset	Both Sexes		Males		Females

Total	♂	1,666	0-73	14.5 ± 0.3	10.0 ± 0.2	11.0	7.0	18.5
	♀	1,533	0-73	15.0 ± 0.3	11.0 ± 0.2	11.5	7.5	20.5

In tables 2 and 3 Q₁ means first quarter and Q₃ third quarter

mum toll at about 6 years, polyarthritis from 6 to 8 years and muscle and joint pains from 8 to 10 years. When valvular disease occurs alone it is most commonly recognized at 9 and 10 years. As incipient manifestations only polyarthritis and valvular lesions are to be found in any considerable number after 15 (chart 3, table 2). Rheumatic fever appears, then, in various forms and each form has statistically an age distribution of its own.

DURATION OF DISEASE

In discussing the duration of rheumatic cardiac disease with emphasis on expectancy it is necessary to speak in statistical terms, although a risk is involved. Such terms have unfortunately been the occasion frequently for much misunderstanding, especially among patients and the families of patients, unless the statistical meaning of the figures is carefully explained. It is the meaning of the word "average" which is important. Average

Chart 5—Rheumatic cardiac disease. Two thirds of all cases begin in childhood, one tenth in adolescence, 20 per cent are fatal in childhood, another 25 per cent in adolescence, less than 25 per cent begin in adult life, about 15 per cent of the patients survive age 45. Periods of life: late maturity 46+, middle maturity 30-45, early maturity males 21-29 and females 19-29, adolescence males 15-20 and females 13-18, childhood males 1-14 and females 1-12. The light barred line indicates the age period in which disease began and the heavy line that in which death occurred. The vertical distance between the two indicates the duration of life.

is the fact that many cases were recorded first not during but shortly after the first attack of rheumatic fever. In the matter of recollection and emphasis it is

figures are misinterpreted and are taken as applicable to individual cases. Fortunately the outlook is not unfavorable. It is a fact that 10 per cent of patients live for more than thirty years (chart 4, table 3). There are, furthermore, records of survival for at least sixty years. In many cases, probably in most, survival is however, less long. But even here the account need not be as gloomy as it is often made to appear, for a fourth of the patients live more than seventeen years. Half, however, die within nine years. If the experience is taken as a whole, the mean duration from onset to death is about thirteen years. There seems to be no essential difference between the sexes. The mean duration of life is 12.5 ± 0.3 years for males and 13.0 ± 0.3 years for females, a difference of 0.5 ± 0.37 , which lies within the range of chance variation.

DURATION OF DISEASE RELATED TO ONSET

There is a difference in duration of expectancy related to age at onset. It may be seen (chart 5) that two thirds (65.3 per cent) of the cases begin in childhood, taken arbitrarily to extend from ages 1 to 12 in females and 1 to 14 in males. On further analysis it appears that nearly a third, 31 per cent, of the patients with onset in childhood (20.1 per cent of total) do not survive this age period, that about another third with onset in childhood, 34 per cent (22.5 per cent of total), do not survive adolescence (18 in females and 20 in males), and that early and middle maturity, taken to end in both males and females at 29 and 45, each claims about one sixth, 17 per cent and 13 per cent (11.0 per cent and 8.2 per cent of total), about 5 per cent go on beyond the age of 45.

Sixty-five per cent of cases begin accordingly in childhood and 10 per cent approximately each in adolescence, early maturity and middle maturity. Three per cent begin after 45.

When the onset of disease is in adolescence and early maturity, only about 15 per cent and 19 per cent of the patients do not survive their own age period and in each group there is a relatively large percentage who live even to advanced age.

There is another way of illustrating the phenomenon which have just been analyzed (charts 6 and 7). This method is reported also because different presentations impress different people with varying degrees of vividness. In this form of representation 70 per cent of cases among males occur in childhood. Each figure in the chart represents 2 per cent of the total group. Twenty-three figures survive the age period of onset and 12 figures succumb. Twenty-three surviving figures pass on into adolescence. Ten and a half of them go

on into maturity, $12\frac{1}{2}$ die. Of the $10\frac{1}{2}$ who go on to maturity only $5\frac{1}{2}$ are alive in middle maturity and $1\frac{1}{2}$ live on into late maturity. Or it may be said that of cases beginning in childhood 66 per cent survive childhood, 30 per cent survive adolescence and 16 per cent early maturity and only 4 per cent go into late maturity. A similar account can be given of the cases which begin in adolescence and in early, middle and late maturity.

Chart 6—Duration of life in series of patients with rheumatic cardiac disease (males). Each figure represents 2 per cent of the total group. White indicates patients living throughout specified period and the black those who died in specified period.

Chart 7—Duration of life in series of patients with rheumatic cardiac disease (females). The symbols are explained in the legend to chart 6.

A statement almost exactly similar to the one just made for male patients can be made for females except that when the disease is acquired in childhood the survival rate is slightly higher in females. As the age at onset advances, it is somewhat more favorable in males (table 4).

DISTRIBUTION OF CASES AT VARIOUS AGE PERIODS

In any view of the distribution of cases of this disease it is desirable to know the numbers to be found at various age periods (chart 8). From the point of view of one whose experience is gained from life in medical clinics, the result is as follows. Sixty-five per cent of all cases are to be found in childhood. In adoles-

cence are found the survivors of those afflicted in childhood (45 per cent) plus the new cases (11 per cent) occurring, of course, in adolescence. This sum amounts to 56 per cent. The number of cases occurring in adolescence is 9 per cent less than in childhood. In early maturity the number afflicted is 42 per cent embracing, of course, the survivors from childhood (23 per cent) and adolescence (9 per cent) plus the new cases which occur at this age period (10 per cent). They amount to 42 per cent of the rheumatic population and exhibit a drop of 14 per cent below the number in adolescence. In middle maturity, constituted of the survivors of the first three classes (26 per cent) to which new cases developing in this age period are added, the percentage has fallen another 6, to 36 per cent. Finally, in late maturity the percentage of survivors from the previous periods (13 per cent) plus the new cases has dropped conspicuously, so that only 16 per cent of all patients with rheumatic fever alive at that time are to be found in this category. It is obvious, therefore, that of the total rheumatic population, the greatest number is found in childhood and that at succeeding age levels the number progressively diminishes the greatest drops being between adolescence and early maturity and between middle and late maturity. Rheumatic fever, in short, is a disease of childhood and early adult life.

SUMMARY

The method employed by the New York Heart Association for gathering data on the natural history of cardiac diseases and for their subsequent statistical treatment shows the value of statistical technique as a tool in the analysis of clinical medicine, with reference, especially, to the public health.

In this study 3,129 patients with rheumatic cardiac disease have been observed, until death, over a period of fifteen years.

There is no important difference between the sexes in the age at onset. The mean age for males is 14.5 ± 0.3 years and for females 15.0 ± 0.3 years.

Rheumatic fever may begin at any age, but it usually begins in childhood, especially between the ages of 5 and 10 years. At 15, 70 per cent of persons afflicted have already acquired the disease.

Chart 8—Rheumatic cardiac disease can be found at all ages. Sixty-five per cent of all rheumatic cardiac disease is found in childhood less is found in adolescence and still less in each subsequent period of life. The periods of life are specified in the legend to chart 5.

In youth, the onset of the disease is characterized by polyarthritis in about half and by carditis or chorea in about one third. In adult life, the onset is characterized chiefly by polyarthritis and, with advancing age, by the appearance of valvular lesions alone.

The mean duration of the disease is about thirteen years (12.5 ± 0.3 years for males and 13.0 ± 0.3 years

for females), 50 per cent of patients die within nine years after onset but 25 per cent live more than seven years and 10 per cent for thirty or more years.

There is a difference in duration or expectancy as related to age at onset. When the disease begins in childhood, 69 per cent survive childhood, 35 per cent

TABLE 3—Duration of Illness

Sex	Number of Cases	Duration in Years				
		Range	Mean	Standard Deviation	Median	Q ₁ Q ₃
Males	1,993	<1-67	12.5 ± 0.3	10.0 ± 0.2	10.0	5.0 17.5
Females	1,136	<1-60	13.0 ± 0.4	10.0 ± 0.2	10.0	5.0 19.0

TABLE 4—Survival Rate by Sex

Period of Onset	Sex	Survival Rate Through			
		Childhood	Adolescence	Early Maturity	Middle Maturity
Childhood	Male	69%	20%	16%	4%
	Female	77%	40%	20%	7%
	Total	63%	30%	18%	5%
Adolescence	Male		89%	67%	26%
	Female		83%	57%	17%
	Total		86%	62%	21%
Early maturity	Male			87%	27%
	Female			78%	18%
	Total			81%	22%
Middle maturity	Male				45%
	Female				47%
	Total				41%

survive adolescence 18 per cent reach the age of 30 and 5 per cent go on beyond the age of 45. When the disease begins in adolescence 85 per cent survive this age period 55 per cent reach the age of 30 and 21 per cent the age of 46 or more. When the onset is in the twenties 23 per cent and when it is after 30, 44 per cent survive the age of 45.

Of all cases of rheumatic cardiac disease 65 per cent are to be found in childhood. In the remaining 35 per cent the disease is acquired at later age periods. In adolescence are to be found 56 per cent, the survivors from childhood plus those who have acquired the disease in this age period. In the age group past 45 are to be found only 16 per cent of whom 13 per cent were first afflicted before and 3 per cent after age 45.

Blind Belief in Laboratory Data—As one who has taught them [medical students] for many years I can see no change in their ability to learn and hold facts that are new to them; that ability is a quality of the trained mind, and it makes little difference how the mind is trained, whether it be in science, or in the humanities or otherwise. Indeed, their scientific training may rise to plague them for it engenders an abiding faith in so-called methods of precision and a blind belief in laboratory data. Just inform the modern student of what the patient complains—never mind about a careful history or physical examination—tell him about the Wassermann, the blood pressure, the blood count, and the urinalysis, give him the results of the stomach wash, the sputum examination, the x-ray of the chest and the gastrointestinal series, and the lumbar puncture, let him know what the blood chemistry—including the plasma proteins and the cholesterol—shows and it may not even be necessary for him to see the patient. He will diagnose your case as quickly as did the doctors of a century ago, who in 1832 knew nothing about these tests and almost as accurately—Iring Frederick C. Safe Deliverance Boston, Houghton Mifflin Company 1942.

CHANCROIDAL INFECTION

TREATMENT AND DIAGNOSIS

MAJOR EUGENE GREENWALD

MEDICAL CORPS, ARMY OF THE UNITED STATES

Chancroid, or *ulcus molle*, is a local, nonindurated, tender ulcer, usually venereal, which is caused by inoculation with *Hemophilus ducreyi*, a gram-negative bacillus, which appears singly or in short chains and is easily obtainable by smears from the ulcer. It is fairly easy to culture if first inoculated into defibrinated rabbit blood and may then best be grown aerobically on dextrose-cystine blood agar slants.¹

INCIDENCE

Chancroid is a relatively common venereal lesion and as such presents problems in diagnosis and treatment to the Army Medical Corps. Of its relative incidence during the World War, the Surgeon General Reports show that though it was the least common of the more frequent venereal diseases comprising 11 per cent of the total, there were 39,044 primary admissions for chancroid in 1917-1918.² The calculated noneffective rate was 0.65 per thousand. Its greatest frequency was among Indian and colored troops, being 34.68 per thousand annually.

The rate for enlisted troops in the United States in 1918 was reported as shown in the accompanying table.³

Rauschkolb⁴ in a civilian clinic found a 66 per cent colored incidence.

The incidence of chancroidal ulcers in females is much less frequent than in the male. Levin⁵ believes that the bacillus may exist in the vagina as a nonpathogenic saprophyte, with the female acting as a symptomless carrier of the disease.

A review was undertaken of all cases of chancroidal infection that had been admitted to the Genitourinary Service, Station Hospital, Fort Belvoir, Virginia, from Jan 1, 1942 to Sept 1, 1942, a nine month period. At this army post, which is an engineer replacement training center, there is an average normal complement of more than one division. The ratio of colored soldiers to white is about 1 to 5. Analysis of the incidence of Ducrey infection reveals 73 colored to 3 white primary admissions during this period, or a ratio of approximately 120 to 1. This disproportion is not carried over to gonorrhea or to syphilis admissions to as great an extent, though the colored rate for the latter diseases is also disproportionately high.

INCUBATION PERIOD

Following sexual contact a three to twelve day incubation period elapses before the onset of the ulcerations, as generally reported. In the cases which we have observed 18 gave histories of sex contacts twenty-two to ninety days prior to onset of clinical symptoms. Little credence was given to the statements of

14 patients because of low intelligence or apparent unreliability. In the remaining 55 cases the incubation period varied between two and fourteen days.

DIAGNOSIS

Clinically, chancroid infection manifests itself as irregular, nonindurated ulcers with a granular, dirty grayish base, covered with a small amount of grayish purulent discharge. The edges are slightly undermined and irregular. The base bleeds easily on manipulation. The ulcers are more frequently multiple than single, this characteristic apparently being dependent on its autoinoculability. It is therefore to be expected that patients with single lesions have had a shorter period from onset to observation. This was found to hold true in this series. Those with single lesions averaged five to eight days before entering the hospital as compared to 10.4 days in cases in which there were multiple lesions.

Most of the chancroidal ulcers appear at the edge of a phimotic prepuce or, in circumcised males, on the frenum and in the coronal sulcus. These areas are those that are most apt to be traumatized during intercourse. Fifty-four per cent of our patients presented themselves with involvement of the inguinal lymph nodes, which are painful in the more advanced stages and are occasionally associated with constitutional symptoms of fever and anorexia.

The diagnosis of chancroid is not difficult. The clinical picture is fairly typical but should be very care-

Rate of Syphilis, Gonorrhea and Chancroid for Enlisted Troops in the United States in 1918

	White	Colored	Ratio W/C
Syphilis	18.83	129.90	1:6.90
Gonorrhea	78.07	514.68	1:6.58
Chancroid	4.98	44.5	1:8.94

fully differentiated from primary syphilis. It is our procedure to do dark fields on four consecutive days, and only after four negative dark field examinations do we feel justified in ruling out syphilis. In only 2 cases have we, during a subsequent four month observation period, had the serologic test for syphilis become positive. In these cases we had failed to identify *Treponema pallidum* on repeated dark field examinations.

In addition to clinical features we have two excellent laboratory aids: the smear and the Ito-Reenstierna skin test. Kornblith and his co-workers⁶ in a series of 175 cases reported that the smear was the best single criterion of diagnosis, positive identification being possible in 88.57 per cent of their cases. In our laboratory the smear is stained by the Gram method. However, other workers prefer Wright's stain or methyl green pyronine. We have found these to be relatively simple procedures and very reliable. In our hands the smear was positive in 65 per cent of the cases.

The skin test is without doubt a specific test, as most investigators agree, though there is some disagreement as to the duration of infection before the skin will manifest an allergic response to the antigen. Becker and Obermayer⁸ state that five weeks is a minimum time

From the Genitourinary Service, Station Hospital, Fort Belvoir, Virginia.

before the skin test becomes positive. Speiser,⁹ however, feels that the test becomes positive within six to ten days following the onset of ulceration.

In performance of the skin test we used a commercial antigen,¹⁰ of which 0.1 cc. is inoculated intradermally. It has been our experience that the skin test was positive in 75 per cent of the cases. In the 20 cases in which the test was either negative or doubtful the duration of infection was short. The lifelong character of a positive Ito-Reenstierna test must, however, be kept in mind and, like the tuberculin reaction, a negative test may be as useful as a positive test in the differential diagnosis.

PROPHYLAXIS

Mechanical as well as chemical prophylaxis following sexual intercourse is frequently urged on each soldier. He receives many lectures by medical and line officers and is exposed to training films concerning sex hygiene at frequent intervals. The chemical prophylaxis which is recommended by the Army consists of (1) initial thorough cleansing of the genitalia with green soap, (2) thorough washing of the parts with 1:1,000 mercury bichloride, (3) urethral injection of 5 per cent mild protein silver and (4) thorough application of ointment of mild mercurous chloride to the parts.

With this method of prophylaxis we find very few failures with respect to syphilitic or gonorrheal infections. However, chancroidal infections are apparently more resistant and we were much surprised on reviewing our prophylactic failures to observe that a disproportionately large number of these had developed chancroid. Whether this disproportion reflects the more chemoresistance of the organism as compared with the gonococcus and *Treponema*, whether the prophylaxis is not being adequately applied to the "danger zones" of Ducrey infection or whether this is a chance circumstance in a relatively small number of cases we are not prepared to state. If this experience is generally corroborated throughout the Army, further investigation is indicated.

In our series 38 per cent of the patients had had a chemical prophylaxis, 29 per cent within one hour or less from the time of exposure. This experience is contrary to the experience of most reports. Thomas¹¹ feels that soap and water thoroughly applied within one hour of the contact is effective. This rate of failure compares very unfavorably to results in gonorrhea and syphilis, in which it comprises no more than 0.8 per cent.

TREATMENT

Until the advent of the sulfonamides the treatment of chancroidal infection was symptomatic rather than specific. During the World War treatment consisted of good local hygiene, under which many chancroids healed spontaneously. However, in progressive cases or very early infections the thermocautery or the chemical cautery were used with varied success as definitive or abortive treatment. Frequently there was extreme tissue destruction and scarring. In 1918 the average non-effective days or time lost from duty represented 24.9 days.²

Since 1918 many therapeutic measures have been recommended, running the gamut from complex mixtures to surgical excision. All of these have been

replaced by the sulfonamide drugs, surgery being indicated only when drainage and exposure of the lesion is extremely poor because of phymosis or paraphymosis. The prognosis has undergone a great change in recent years, since sulfonamides have been found useful.¹²

Prerequisite to the intelligent treatment of penile lesions is the recognition of the frequency of mixed infections. It is our practice to search for *Treponema pallidum* repeatedly in penile lesions subsequent to the positive diagnosis of Ducrey infection, withholding all local therapy until a minimum of four consecutive dark field examinations have been found negative. During this period treatment with sulfathiazole is initiated by mouth. In our experience, often necrotic and heavily secondarily infected lesions become clean and *Treponema* is then more easily found in the expressed serum.

In this series we have found a chancroidal lesion coincident with syphilis in 10 instances. These cases presented, however, no problem in therapy for no adverse reaction marked the simultaneous use of sulfathiazole and daily full doses of mapharsen as used in our clinic in the treatment of primary syphilis.¹³

Once the diagnosis of Ducrey infection is made our routine consists in the administration of sulfathiazole in 4 Gm. daily doses, the initial dose being 2 Gm. The drug is continued in these doses for a minimum of seven days with careful observation for toxic phenomena. In no case in this series was there indication for withdrawal of the drug because of toxicity.

After a minimum of four negative dark field examinations, during which local application of saline dressings was used, the lesions were treated twice daily with soaks of 1:8,000 potassium permanganate followed by the application of sulfanilamide powder.

RESULTS

Under this regimen all patients rapidly improved with an average of 7.6 days of time lost from duty. No patient was discharged from the hospital until the lesions had completely epithelized.

Ten per cent of our cases were admitted with fluctuant buboes and surgical intervention was necessary in all of these, since treatment by sulfathiazole alleviated none. In 3 cases it was noted that on admission the nodes were discrete and in spite of favorable response of the ulceration to treatment the nodes went on to supuration and had to be incised and drained.

There were six recurrences in this series, four of which had received less than seven days of treatment. One of these patients had received only local treatment for five days on his primary admission. Another had a mixed infection with primary syphilis. One case listed as a recurrence was probably a reinfection since there was a time lapse of ninety-two days between his first and his second admission. On readmission all of these responded well to combined local and systemic therapy as outlined.

It is customary in our clinic to follow all cases of genitoinfectious disease not diagnosed as syphilis by weekly serologic tests for syphilis for one month and monthly Kahn tests for three months thereafter. However, since this post is a training center, many of the patients are transferred to other stations and field organizations. About 32 per cent of our patients were thus lost. The remaining 68 per cent have remained

consistently seronegative except for 2, who within four weeks returned with a positive blood test and were subsequently treated for early syphilis. Of these 2 patients 1 had had a negative smear and negative skin test but was repeatedly negative on dark field examination and clinically was considered to have an early chancroidal ulcer. The second patient gave negative smear and positive skin tests and also healed rapidly with sulfathiazole therapy. The diagnosis of chancroid in these 2 cases is open to question despite the fact that the lesions healed without antisyphilitic treatment.

SUMMARY

1 The ratio of colored to white soldiers having Dickey infection is much higher than the similar ratios for syphilis and gonorrhea.

2 The diagnosis of chancroid is aided by reliable procedures of smear and skin test.

3 Primary syphilis must be carefully differentiated from chancroid by multiple dark field examinations.

4 In our experience, prophylaxis by army routine fufals to protect against chancroid as well as it does against syphilis and gonorrhea.

5 Treatment with sulfathiazole in 4 Gm daily divided doses for seven days is reliable and free of dangerous complications.

CHEMOTHERAPY IN CHILDHOOD
SEPSIS

ABRAM KANOF, MD

ISIDOR LEBER, MD

AND

BENJAMIN KRAMER, MD

BROOKLYN

The literature of the past five years has been rich in papers describing all phases of sulfonamide therapy. The pharmacology of these compounds has been ably reviewed by Marshall¹ and by Goodman and Gilman.² Long and his associates³ have thoroughly described the clinical uses and toxic manifestations. In the pediatric literature, Silverman⁴ has contributed a critical review of the subject and Bigler and Haralambie⁵ have published an exhaustive article particularly excellent for its historic and pharmacologic background.

Very few of these papers have been devoted specifically to the chemotherapy of septicemia. The most complete article is that of Herrell and Brown,⁶ which, however, deals with adult cases. Hamburger and Rueggsegger⁷ have described 12 cases, and Rammelkamp and Keefer⁸ have reported 7 cases of staphylococemia treated with these drugs. Others who have

reported small series of cases of staphylococcal septicemia treated with the sulfonamides have been Thornhill, Swart and Reel,⁹ Goldberg and Sachs,¹⁰ Weisman and Russell,¹¹ Carroll and his associates¹² and Herrell and Brown.¹³

The chemotherapy of pneumococcal septicemia has been described by Dyke,¹⁴ and many such cases were included in the comprehensive report on the treatment of pneumococcal infections in children by Barnett, Hartmann and Perley.¹⁵ No article has been devoted solely to streptococemia but individual case reports have been plentiful in various articles¹⁶ and in the symposium on the subject which appeared in the *Journal of Pediatrics*.¹⁷

The present paper is a study of the effects of the sulfonamide drugs on the mortality, morbidity and incidence of septicemia in the pediatric service of the Jewish Hospital of Brooklyn. Since 1937 we have treated 104 patients with the following drugs: sulfanilamide, sulfamethylthiazole, sulfapyridine, sulfathiazole and sulfadiazine. In making this study we have used as controls a series of 320 septicemia patients treated before the advent of the sulfonamides. This older series was shown in an exhibit at the New York Academy of Medicine in 1940. The purpose of our exhibit then was to demonstrate that the prognosis in septicemia depends not only on the infecting organism but also on certain other factors.

FACTORS INFLUENCING OUTCOME

The factors influencing the outcome in septicemia are the age of the patient, the type of pharyngitis accompanying the sepsis, the size of the bacterial invasion, the shift to the left in the count of the polymorphonuclear blood cells, the presence of localizations in certain organs and enlargements and the severity of the particular infection at the time the patient happens to be sick.

We should like to explain what we mean by three of these factors.

1 *Type of Pharyngitis*—We have placed sore throat, in accordance with its severity, into two divisions.

(a) *Severe Pharyngitis* (pharyngitis predominating or presenting). In this type the throat is acutely and severely inflamed, with the pharyngeal wall and tonsillar fauces severely congested and red at the time that the bacteremia is found.

(b) *Mild Pharyngitis* (pharyngitis nonpredominating, nonpresenting). In this type the throat, though diffusely red, does not appear angry or severely inflamed.

The charts were prepared by Mr. Henry Moore from the Department of Pediatrics of the Jewish Hospital. Read before the Section on Pediatrics at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

The practical and theoretical implications of this point of view have been discussed in a previous paper,¹⁸ but here it is sufficient to state once more that the type of accompanying pharyngitis has a decided influence on the mortality rate

TABLE 1—Year by Year Mortality in Sepsis

Year Ending July 31	Death from		
	Staphylococcal Septicemia	Streptococcal Septicemia	Pneumococcal Septicemia
1931	40%	48%	40%
1932	62%	44%	28%
1933	75%	70%	15%
1934	75%	70%	55%
1935	90%	50%	50%

2 *Size of Invasion*—We should also make clear what we mean by this factor. In a small invasion the broths are positive but the plates remain sterile. In a medium invasion the plates show a growth but

of treatment will not be presented in terms of gross mortality. Rather, the mortality will be given for each subgroup when treated with sulfonamide and when not thus treated.

CHEMOTHERAPY IN STREPTOCOCCUS HEMOLYTICUS SEPTICEMIA

Chart 1 shows that the use of the sulfonamides has reduced the gross mortality rate to one fifth its previous level. Moreover, it shows that in these 15 treated cases of streptococemia the difference in mortality between subgroups is still present but that in each subgroup the mortality is less in the sulfonamide treated patients.

Table 2 lists the details of treatment in these cases.

Six of these patients are especially interesting because they are children who probably would have died in the presulfonamide days. Among them were a 3 and a 6 weeks old infant, with streptococcal meningitis and streptococemia. One of the 2 also showed sacral edema, a finding which, as is shown by chart 1, was invariably

TABLE 2—Streptococemia Treated with the Sulfonamides

Case	Age	Drug	Administration			Highest Blood Concentration	Final Result	Size of Invasion	Drug Reaction	Comment
			Oral	Subcutaneous	Intravenous

there are less than ten colonies per cubic centimeter of blood. If there are more than ten colonies per cubic centimeter of blood on the plates we call it a large or massive invasion.

3 *The Yearly Invasion in the Mortality*—The importance of this factor is shown in table 1.

Our conclusion at that time was that the gross mortality percentage is not a satisfactory expression of prognosis in septicemia. Study of chart 1, for example, will show that whereas the gross mortality in streptococemia was 55 per cent, the mortality in certain subgroups was as low as 14 per cent and in others as high as 100 per cent. The gross mortality in pneumococcal sepsis was 46 per cent (chart 2), but some subgroups had a mortality of 16 per cent while other subgroups of pneumococcal septicemia suffered 100 per cent mortality. In staphylococcal sepsis the mortality varied between 23 per cent in one subgroup and 93 per cent in another (chart 3).

In the present paper the results of chemotherapy are analyzed with these principles in mind. The results

fatal. Two other children had lymphatic leukemia with septicemia as a complication. Under chemotherapy, both children recovered from the bacterial invasion, their total white count dropped and the polymorphonuclear cells disappeared. The leukemic picture reappeared when the drug was discontinued. The fifth patient was a 9 month old baby who though he had considerable distention, numerous petechiae and Cheyne-Stokes respirations nevertheless recovered. The sixth recovered despite the presence of pneumonia, pericarditis, considerable distention, hematemesis, icterus and edema of the abdominal wall, forearms and clavicular regions.

Of the 2 children who died, 1 was treated in the early days of sulfonamide drug therapy. He received doses of sulfanilamide which we now consider inadequate, and such complications of the septicemia and pneumonia developed as emphysema, appreciable hepatic enlargement, repeated convulsions, induration of various parts of the skin, considerable distention and cyanosis. The other child who died was a 10 month old baby with pneumonia, mediastinitis and paralytic ileus who was not treated with sulfapyridine until eight hours before his death.

18 Kanof, Abram, and Kramer, Benjamin. Relation of Sepsis to Infections of the Respiratory Tract. *Am. J. Dis. Child.* 60: 1067 (Nov.) 1940.

CHEMOTHERAPY IN STAPHYLOCOCCIC SEPTICEMIA

Chart 3 shows the influence of the sulfonamides on the prognosis in staphylococcemia. Forty-five patients were treated. The gross mortality in this treated series was 46 per cent as against 69 per cent in the untreated patients. Study of this figure leads to certain striking observations applicable to both treated and untreated patients. It shows that some subgroups are affected by chemotherapy while others are refractory to such therapy. These observations may be summarized as follows:

1 The mortality of both treated and untreated patients remained extremely high when there were foci in the bone and viscera.

2 The mortality also remained extremely high in patients who had involvement of the lungs and foci in other viscera.

3 However, when the bone alone was involved the mortality was 23 per cent in untreated patients and zero in the treated group.

4 When the lung alone was involved the mortality was 82 per cent in the untreated and 28 per cent in the treated group of patients.

Chemotherapy reduced the mortality also in those groups of patients with staphylococcemia who had diarrhea. Specific drug therapy was beneficial also in patients under 1 year of age, those having large invasions, abdominal distention, subcutaneous abscesses or pustules or a blood which showed a polymorphonuclear shift to the left and those whose temperature curve was persistently below 103 F.

The patients treated with sulfathiazole or sulfadiazine showed the best results. Twenty-three were treated and 7 (30 per cent) died. Three died soon after admission and before adequate blood concentrations could be established. The only fatality under sulfadiazine therapy was among these 3. The fourth child died with myelogenous leukemia despite sterilization of the blood stream. Of the 16 who recovered on sulfathiazole or sulfadiazine therapy, 12 were under 1 year and several had multiple localizations. One was a 5 day old child with icterus gravis neonatorum and omphalitis with septicemia.

The mortality rate was 73 per cent among 15 patients treated with sulfanilamide or sulfapyridine or the two combined. The 4 who did recover had localizations that made for a good prognosis even in the presulfonamide days: 2 had cellulitis, 1 had osteomyelitis and 1 had pneumonia.

The 7 patients treated with sulfapyridine combined with sulfamethylthiazole fared better. 4 recovered. Moreover, all 4 who recovered were under 1 year of age and had a large blood stream invasion. Two of the recoveries were quite dramatic. One occurred in a 6 week old infant who had a large blood stream invasion with multiple lung abscesses and empyema. The other occurred in a 3 day old child with erythroblastosis, pneumonia and staphylococcemia. This child was first treated with sulfapyridine, but the blood did not become sterile until sulfamethylthiazole therapy had been employed.

There were also 2 patients in whom a change from sulfathiazole to sulfadiazine seemed to influence the course of the disease. One was a 10 day old infant with acute pharyngitis, diarrhea and dehydration and generalized furunculosis. He was given sulfathiazole for nine days, but new lesions continued to appear daily and the blood culture remained positive. Shortly after sulfadiazine therapy was begun recovery took place. The second infant, 18 days old, with osteomyelitis of the femur and multiple cutaneous and subcutaneous foci, did not respond to sulfathiazole but recovered promptly after administration of sulfadiazine.

There are indications that the prognosis in staphylococcemia will improve as our experience in the handling of the older sulfa drugs increases and as new drugs of this group are discovered. Chart 4 shows that each year since 1937 the prognosis in staphylococcemia has improved. Of the last 23 patients treated with sulfathiazole or sulfadiazine only 30 per cent died.

Chart 1—Factors in the prognosis of streptococcemia in treated and untreated cases. The following factors seem to have no influence on the prognosis: tonsillectomy, loss or gain in weight during illness, previous illnesses, pathologic urinary findings, convulsions (without organic lesions), meningismus, anemia, and type of temperature curve.

CHEMOTHERAPY IN PNEUMOCOCCIC SEPTICEMIA

Chart 3 shows the mortality in pneumococcic septicemia. Sixteen patients were treated with the various sulfonamides. Thirty-one per cent died as against 46 per cent in the group of untreated patients. This does not seem a great improvement until one considers that since the use of the sulfonamides a greater portion of the pneumococcemia patients suffered from large invasions (table 2). Before sulfanilamide, 38 per cent of patients with pneumococcemia had a large invasion. In the present series 68 per cent had a large number of organisms in the blood. Of the pneumococcemia patients with large invasions, 84 per cent died in the presulfonamide era, in the treated series only 25 per cent died.

In chart 2 one sees that only 50 per cent of the patients with severe pharyngitis died, as against 100 per cent in the untreated group. Furthermore, in the

treated series only 1 of 3 patients with erysipeloid or petechiae died, while in the earlier series 89 per cent died. Finally, of 7 patients in the new series who had a shift to the left, only 42 per cent died, while in the untreated series there was a fatal outcome in 67 per cent of the group.

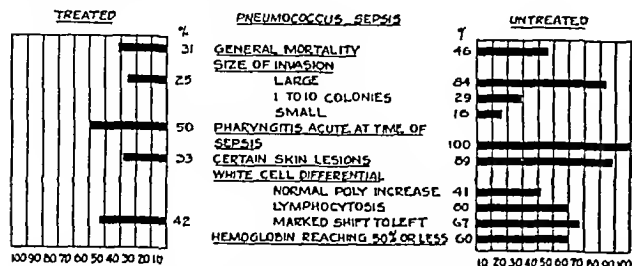

Chart 2—Factors in the treatment of pneumococcal sepsis. Certain skin findings include petechiae, edema, necrosis, erysipeloid and deep hemorrhages. The lung is so predominantly the localization in pneumococcal sepsis that there are too few cases from which to judge the influence of other types of localization, when such others appear it is usually in association with a large invasion and a fatal outcome. The age of the patient is no factor in the prognosis of pneumococcal sepsis; neither is the state of nutrition, splenomegaly or hepatomegaly, birth weight, previous illnesses, tonsillectomy or pathologic urinary findings.

One of the patients died within twenty-four hours after admission, before the full effect of sulfapyridine therapy could have been established. Two patients in the series who had meningitis died, in contrast with the 2 patients with streptococcal sepsis who survived this complication.

The details of these cases are shown in table 3.

ESCHERICHIA COLI SEPTICEMIA

We have had 8 patients with *Escherichia coli* septicemia who were treated with these drugs. Three died and five recovered. One of those who recovered was only 5 days old. One was 2 months old and also had *Staphylococcus aureus* in the blood stream. We have shown that before the sulfonamide era patients with two organisms in the blood stream invariably died.¹⁹

EBERTHELLA TYPHOSA SEPTICEMIA

Two patients with *Eberthella typhosa* septicemia were given the benefit of chemotherapy. They were 9 and 10 years of age, 1 died (treated with sulfanilamide) and 1 recovered (treated with sulfapyridine).

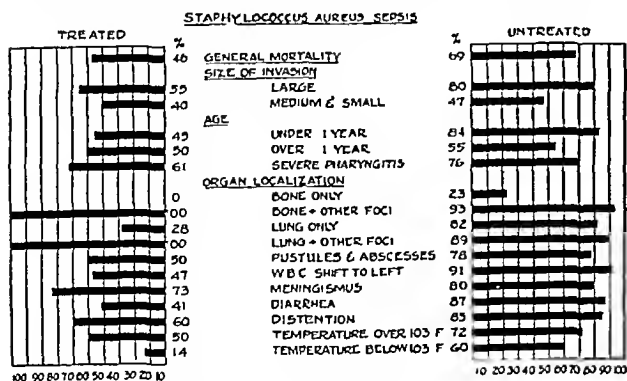

Chart 3—Factors in the treatment of staphylococcal sepsis.

One patient 2 weeks old with *Salmonella paratyphi* septicemia died despite treatment with sulfanilamide.

One child aged 10½ years, with *Proteus vulgaris* septicemia recovered on sulfanilamide therapy. One with *Pseudomonas aeruginosa* in the blood recovered on sulfanilamide therapy.

19 Kanof Abram and Kramer Benjamin. Multiple Invasion of the Blood Stream. *J Lab & Clin Med* 27: 173 (Nov) 1941.

A patient aged 18 months with *Salmonella typhi* murium and *Staphylococcus aureus* in the blood stream recovered with sulfathiazole and sulfadiazine.

Three patients with *Hemophilus influenzae* sepsis and meningitis, all about 3 years of age, received sulfanilamide, 2 died and 1 recovered. One patient extremely sick with meningitis and meningococcal sepsis recovered with sulfanilamide therapy.

Two patients suffering from subacute bacterial endocarditis with *Streptococcus viridans* in the blood died despite treatment with sulfanilamide. One received sulfapyridine in huge doses and 1 received sulfapyridine and sulfadiazine in conjunction with fever therapy. We have had 8 patients with *Streptococcus gamma* septicemia, but these presented so variegated a clinical picture that we have not attempted to analyze the results. Three of these patients died.

THE EFFECT OF CHEMOTHERAPY ON MORBIDITY

Chart 5 shows the influence of these drugs on the morbidity as measured by the duration of fever. Of the untreated patients with septicemia who recovered, 80 per cent were sick for more than two weeks and 42 per cent for more than thirty days. Of the treated patients, 30 per cent were sick longer than two weeks but only 6 per cent for more than thirty days.

Chart 4—Improving mortality in cases of staphylococcal sepsis with sulfonamide therapy. Year by year mortality.

ROLE OF THE SULFONAMIDES IN THE PREVENTION OF SEPSIS

The role of the sulfonamides in the prophylaxis of septicemia has been reported in only a few instances. Thomas, France and Reichman²⁰ have reported its use in the prophylaxis of rheumatic fever. Gray and Gear²¹ found sulfapyridine of some value in reducing the number of carriers during an epidemic of cerebrospinal meningitis, while Hochberg and his associates²² found it of value in reducing postoperative pneumonia in dogs. Smith²³ found these drugs of no value in preventing acute tonsillitis during an epidemic, though the drugs were of definite value in combating the disease. Hoare²⁴ did not find them of value in preventing postpartum infections.

We have been interested in the possible effects of the widespread use of the sulfonamides in relatively mild infections on the prevention of septicemia. We have attempted no systematic, citywide survey, but we have relied on tabulations of the incidence of septicemia in proportion to the total number of admissions at the

Jewish Hospital of Brooklyn This has been done for each type of sepsis for the years preceding and the years following the introduction of the sulfonamide drugs In addition, we have also studied the differences in the clinical picture of sepsis before and since the use of these drugs in infectious illnesses

Table 4 shows the yearly incidence of the three major forms of septicemia at the Jewish Hospital since 1931 It shows that from 1937 onward there was a decided drop in the incidence of streptococcus hemolyticus septicemia and pneumococcal septicemia However, there was no drop in the incidence of staphylococcal septicemia, and in 1940 and 1942 there was actually a rise in the occurrence of this form of sepsis The table shows that there was no important variation in the total number of pediatric admissions throughout these years

There have been two important changes in the clinical picture of staphylococemia as seen in our service since the sulfonamides have been in general use The first has been a shift in the age incidence Table 5 shows

Before the use of the sulfonamides, 41 per cent of the patients had bone foci and 27 per cent had pulmonary localizations Since the sulfonamides have been in

TABLE 5—Percentage of Total for Each Organism Occurring in Each Age Group

staphylococemia have occurred in children under 1 year, and only 12 per cent in children of school age

The other variation has been a change in the frequency of certain localizations in this form of sepsis

have found no change in the incidence of localizations in the skin, peritoneum, intestinal tract, brain or kidneys

We have also found a change in some of the clinical aspects of pneumococcal septicemia We¹⁸ reported in the presulfonamide period that in a group of patients we studied 60 per cent of pneumococcal sepsis consisted of a small transient invasion of the blood stream by the pneumococcus in the course of a severe pneumonia In only 35 per cent of the total was the invasion a large one, with localizations in the meninges, heart or bone In this group, moreover, the patients were often suffering from a predisposing illness such as chronic glomerular nephritis, congenital heart disease, prematurity or celiac disease A study of table 3 will show that this particular picture has changed Among 15 patients with pneumococemia encountered since the general use of sulfonamides only 2 had pneumonia Furthermore, 68 per cent of these patients had large invasions in contrast to 38 per cent reported¹⁸ in the presulfonamide era There has also been a change in the age incidence of pneumococemia Table 5 shows

that before 1938 the cases of pneumococcemia were evenly distributed throughout the years of childhood. Since 1938, however, we have not seen pneumococcemia in children over 6 years of age. This may perhaps be attributed to prompt and effective treatment of children suspected of having pneumonia in this age period.

Chart 5—Morbidity among patients who have recovered from septicemia with and without chemotherapy

REACTIONS AND BLOOD CONCENTRATIONS

We have encountered only 5 patients who have had an adverse reaction to drug therapy. Two of these had severe cyanosis while being treated with sulfanilamide. Two patients on sulfadiazine therapy developed hematuria. One patient on sulfadiazine therapy developed leukopenia. All these untoward symptoms subsided when the drug was withdrawn.

Chart 6 shows the concentrations of the sulfonamides in the blood reached in the treatment of these patients. Two facts are worthy of note. First there is no correlation between the concentration of the sulfonamide and the outcome. Second, the highest concentrations were consistently reached when sulfadiazine was used.

Chart 6—Blood concentrations in patients treated with various drugs

COMMENT AND SUMMARY

In this study we have emphasized the importance of certain clinical factors in establishing the prognosis in childhood septicemia. The prognosis in a particular case depends not only on the organism causing the infection but also on the age of the patient, the type of pharyngitis accompanying the sepsis, the size of the bacterial invasion, the reaction of the hemopoietic sys-

tem as judged by the shift to the left in the count of the polymorphonuclear white cells, the presence of localizations in certain organs and the virulence of the infection in the particular year.

Using as controls a series of patients in whom the influence of these factors was studied in the years previous to sulfonamide therapy, we have established that there is a definite reduction of mortality in patients treated with the sulfonamide drugs. However, there is still a difference in the mortality of different subgroups of the same type of septicemia. We have found, further, that the duration of illness has been sharply reduced in the treated series.

A further finding of importance is that coincident with the use of the sulfonamide drugs there has apparently been a lowered incidence of admissions to our service of patients with pneumococcemia and streptococcemia. Surprisingly, however, there has been no decrease in the frequency of staphylococcal septicemia.

Before 1938 most cases of pneumococcal sepsis presented a bacteremia, transient and small, which was merely an incident in the course of a severe pneumonia. With the use of the sulfonamides the cases of pneumococcemia which still are seen have most often been represented by severe nonpulmonary infections with large blood invasions and multiple localizations. Moreover, it seems now to have become a disease of infancy rather than an illness of the school age child.

Staphylococcal septicemia has changed in two important respects. Before the sulfonamide period the disease was most often associated with localizations in the bone. Recently this has not been true, the most frequent localizations have been in the lung. A second development has been in the shift of age incidence to the first year of life.

80 Linden Boulevard

ABSTRACT OF DISCUSSION

DR REUBEN OTTENBERG, New York. I want to point out the wide variation in mortality from year to year in the statistics. That must warn us to go carefully in interpreting improvement. On the other hand I have to agree with the general trend of everything Dr Kanof said. Every one who has used the sulfonamides has found a vast improvement in the results in septicemia due to the streptococcus and to the pneumococcus, and some improvement when it is due to the staphylococcus. The overall reduction in the case of the staphylococcus, as the authors pointed out, is a small figure. A third of the staphylococcus cases were treated with sulfanilamide or sulfapyridine, which we now know are relatively inefficient. In the latter part of the series which, I presume, received sulfathiazole, there was a much better result and in the cases treated with sulfadiazine there was only one death, it is apparent that the result depends to a considerable extent on the drug. Septicemia is not a single disease, it is a multitude of diseases all of which are characterized by bacterial invasion of the blood. Before we had the sulfonamides, the most important point in treatment was the eradication of the infecting focus. The introduction of the sulfonamides must not make us omit the attempt to find and remove the focus which is feeding bacteria into the blood. Our failures with sulfonamides were due mostly to the impossibility of finding the focus or of treating it surgically. The fact that frequently today we cure cases without doing anything to the focus should not make us forget that there are still failures with the sulfonamides and that the focus is there. We thought, three or four years ago, that failure was due to inability of the sulfonamides to penetrate the lesion. We now know, as the result of the work of Lockwood and particularly of D. D. Woods of England, that the failure to cure the local lesion is due to the presence of protein breakdown products in the local lesion or possibly, although that has not yet been proved, of para-aminobenzoic acid. The most important observation in

the paper is not the diminished mortality but the diminishing incidence of streptococcal and pneumococcal septicemia in the years since we have had the sulfonamides. Perhaps this is going to be an instance in which the instincts of the general practitioner were right. The experts, for the most part said "You must not give sulfonamides in ordinary ear aches and ordinary sore throats, the danger of hemolytic anemia and agranulocytosis is too great." The general practitioner has gone his way and given the drug to most of these patients. We shall need more evidence, but it looks as though the general practitioner may have been justified.

DR. GEORGE J. BOHNS, Wilmington, Del. About two years ago Dr. Osgood of Oregon suggested that in cases of *Staphylococcus aureus* septicemia, in which the sulfonamide drug was not effective, recovery might result if neoarsphenamine was added. We had such a case in a boy 12 years of age who had *Staphylococcus aureus* septicemia and meningitis and the sulfonamide drugs sulfapyridine and sulfathiazole were not effective, but as soon as neoarsphenamine was given along with these drugs prompt recovery occurred. I should like to ask the authors if they had any such cases.

DR. BENJAMIN KRAMER, Brooklyn. Statistically, it is wrong to compare the mortalities of one year with another year and conclude that, because a certain drug has been used, the result is necessarily attributable to the drug. However, the results here in certain groups of cases are so striking that there can be no doubt as to the general effectiveness of these drugs not only in adult sepsis but also in childhood sepsis. One of the particular contributions of this paper is that it calls attention to certain conditions other than specific therapy which influence prognosis and therefore indicates that in any study of the effectiveness of the sulfonamide drugs one has to break down the entire series of cases in order properly to evaluate the effects of treatment. When you do that, it is obvious that there are certain conditions which interfere or completely negate the effects of the treatment. This is important because it constitutes a challenge in that it indicates that the drug itself is not effective, that the drug is not reaching the focus of infection, that the bacteria produce some chemical substance which neutralizes the drug or that some other factor as yet unknown is operating. What some of these factors may be, Dr. Ottenberg has indicated. Another important contribution is the study of the effect on morbidity. This, while it is one of the interesting phases of the paper, is yet one of the weakest, considering the conditions under which we had to work, namely to limit our study to the types of cases admitted to the service, their severity in relation to the total number of cases admitted and to the types of cases previously admitted. However, the results are sufficiently suggestive, perhaps, to warrant a more systematic, more comprehensive and perhaps a better controlled study along the same lines. Anybody who has practiced pediatrics or even medicine in the presulfonamide days and is still active today must realize the striking change in the incidence of certain types of infections. While we have no convincing evidence that the change has been produced by the use of sulfonamide drugs, the evidence that we have is certainly suggestive.

DR. ABRAHAM KANOF, Brooklyn. Dr. Ottenberg and Dr. Kramer emphasized that there are natural factors which influence the mortality and morbidity. This is the important part of the paper. Just to say that the mortality in staphylococcal sepsis is 60 per cent before treatment and 30 per cent after treatment does not tell the story. It varies without sulfanilamide or sulfathiazole from year to year, and with different subjects, and that is a point which we wanted to emphasize. Dr. Ottenberg brought up the question of multiple blood stream invasions. Dr. Kramer and I reported a series of cases of multiple blood stream invasions about six months ago and classified multiple blood stream invasions into four groups. In the first group one gets two organisms in the same culture. In our experience, those cases were invariably fatal. In our second group there is one organism on one occasion and another one in a subsequent culture. For example, one may see a youngster who has a staphylococcal septicemia, who goes along for three or four weeks, has an occasional positive staphylococcus blood culture and then suddenly develops an erysipeloid rash, and one takes a blood culture and finds a

hemolytic streptococcus. Most of those patients died, although some recovered. A different type of multiple blood stream invasion is one in which a variant of the first organism appears in a subsequent culture. One may have a patient with a *Streptococcus hemolyticus* septicemia who shows two or three positive cultures with that organism. Then one day a culture of the blood reveals *Streptococcus viridans* or gamma streptococcus. Those are also considered multiple blood stream invasions, but they usually end in recovery. The fourth is the type in which the second organism is a casual invader. A youngster has a positive typhoid in the blood on one or two occasions and then when nearing convalescence one finds that he has a gamma streptococcus in the blood. In the first group, in which there are two organisms in the same blood culture, the patient invariably died before the era of the sulfonamides. Now we have 2 such patients who recovered on sulfathiazole.

TESTOSTERONE PROPIONATE PELLET IMPLANTATION IN GYNECIC DISORDERS

ROBERT B. GREENBLATT, M.D.

AUGUSTA, GA.

The employment of so-called "male" sex hormone in the treatment of certain gynecic disorders may appear paradoxical but it is not unphysiologic. Androgenic hormones are not peculiar to the male, for they are elaborated also by the female. The Callows,¹ Womack and Koch² and others have isolated from the urine of normal women the same two androgens identified in the urine of normal males. It is reasonable to suppose that in woman's hormonal economy androgens play some physiologic role.

In recent years there has been an increasing trend to use androgens in gynecologic therapy. This practice has received much support, much condemnation. The schism is wide. Two diverse opinions, each crystallized from a wealth of experience, are found in the statement of Geist and Salmon³ that "the use [of androgens] as therapeutic agents has a sound rationale" and the contention of Hamblen⁴ that "androgens have no place in rational gynecologic therapy."

A rapidly accumulating literature has established many therapeutic uses for these steroids in woman.⁵ The parenteral, oral or percutaneous route of administration may require massive doses to assure therapeutic results, and this may not be attended always by balanced physiologic reactions. It must be admitted that after large parenteral doses (500 mg. a month) undesirable side reactions such as temporary or permanent virilism may develop.⁶ Such doses used parenterally have

given cause for protestation that androgens are contrasexual. It may well be that the dose and not the hormone is contraphysiologic.

It has been noted by many investigators⁷ in both animal experimentation and clinical investigation that implantation of pellets of crystalline steroids results in

Fig. 3.—Percentage absorption curve for 100 mg pellets of testosterone propionate obtained by plotting percentage absorption of eleven pellets recovered at intervals varying from thirty six to one hundred seventy seven days.

a slow and more physiologic absorption of the substance than that observed after parenteral administration. Since the amount of hormone released to the organism is continuous though minute in quantity, it is conceivable that by this method all the beneficial effects of larger doses of androgens may be obtained without the arrhenomimetic phenomena. This paper deals with my observations following the implantation of pellets of testosterone propionate for the therapy of various gynecic disorders.

MATERIAL AND METHODS

Sixty-four women ranging in age from 19 to 53 had pellets of testosterone propionate implanted subcutaneously. From 1 to 4 pellets were implanted at one time. The pellets varied in weight from 22 mg. to 200 mg. Though the average dose was about 100 mg., nevertheless as little as 22 mg. and as much as 400 mg. was employed. Sixty-eight implantations were performed on 64 patients, of whom 61 had but one implantation. One patient had three and 2 had two implantations. Studies were conducted on patients presenting a variety of gynecic disorders, namely functional uterine bleeding, uterine fibromyomas with or without menstrual disturbances, dysmenorrhea, menopausal syndrome and nervous tension states. Attention was given to coincident disturbances of micturition and the status of the patient's sexual libido before and after implantation.

Vaginal smears, endometrial biopsy studies and blood chemistry determinations were obtained in the majority of cases before implantation and were repeated at various intervals after implantation. Many vaginal biopsy studies were also taken before and after implantation. The patients were seen, as a rule, at weekly to monthly intervals and have been under observation from four to twenty-two months.

PROCEDURE

All implantations were made under sterile conditions in the operating room. The skin of the abdomen was prepared and then an area between the pubis and the

umbilicus 3 cm. long was infiltrated with 1 per cent procaine hydrochloride down the midline to the rectus sheath. An incision was made through the skin and subcutaneous fat and the rectus sheath was visualized. A small incision was made in the sheath exposing the rectus muscle. The pellet, or pellets, were then inserted under the sheath to lie on top of the muscle belly. The fascial sheath was closed with No. 1 chromic catgut and the skin and subcutaneous fat approximated by silk stay sutures.

FUNCTIONAL MENOMETRORRHAGIA

Eight patients with severe functional menometrorrhagia of from three months' to two years' duration had submitted to curettage and/or a variety of therapeutic procedures with disappointing results. Implantation of testosterone propionate pellets in doses varying from 96 to 205 mg. was soon followed by cessation of bleeding in every case (fig. 7). It is noteworthy that in 5 of the patients bleeding was known to be associated with cystic glandular hyperplasia or persistent estrogenic endometria. In 3 cases, in spite of the control of flooding episodes, repeated suction curettages revealed persistent hyperplasia or estrogenic endometria for many months after pellet implantation. Stabilization of the menses was the rule, though temporary cessation of the menses or an increase in the interval between periods frequently occurred. In 2 cases menorrhagia was associated with an imperfect progesterational endometrium. Following implantation normal cyclic bleeding occurred from an improved progesterational endometrium. Two patients with menorrhagia not benefited by this procedure were excluded from this group because of concomitant pelvic inflammatory disease.

MENOMETRORRHAGIA ASSOCIATED WITH UTERINE FIBROIDS

Twelve patients with severe menometrorrhagia associated with uterine fibroids had been hospitalized but were considered poor risks for major surgery. Pellets of testosterone propionate were implanted in doses of

Fig. 5.—Compare original size pellet with size of recovered pellets. A four 25 mg. pellets recovered one hundred and thirty three days after implantation. B four 100 mg. pellets recovered one hundred and seventy seven days after implantation.

from 25 to 302 mg. Subsequently, though the degree of flooding was less in all but 1 case, nevertheless the results were very poor in 3 cases (8, 9, 11) and hysterectomy was performed six to seven months later. Of the 3, 2 presented submucous fibroids and 1 multiple fibroids with pelvic inflammatory disease. In a fourth

P., Emerson Kendall Jr. and Firor W. M. Treatment of Addison's Disease with Pellets of Crystalline Adrenal Cortical Hormone (Synthetic Desoxycorticosterone Acetate) Implanted Subcutaneously. *Bull. Johns Hopkins Hosp.* 64: 339 (May) 1939.

(case 7) there was moderate improvement in the degree of menorrhagia for thirteen months, then bleeding episodes began to recur. In the remaining 8 cases satisfactory alleviation resulted, and in some of these for as long as eighteen to twenty-two months. Testosterone propionate pellet implantation proved of value as a

temporary measure, affording an opportunity for enough improvement in the patient's physical condition to permit ultimate major surgery (cases 3 and 12). It was not meant as a substitute for surgery. The endometrial studies in case 5 are of interest, for this is the only instance in the series in which testosterone propionate pellets suppressed further ovulation. The patient was 45 years of age and had flooded for two to three weeks in every month for about two years. At the time of implantation of a 100 mg testosterone propionate pellet, suction curettage revealed an imperfect progestational endometrium. One month later she bled from a progestational endometrium. Thereafter the interval between the menses increased and repeated suction curettages at various intervals revealed an estrogenic or hypostrogenic endometrium. She has not menstruated in the past year. This may be coincidental. On the other hand, this may be an example of premenopausal bleeding being tided over a crucial period by pellet implantation (fig 8).

HYPERMENORRHEA-POLYMENORRHEA

Hypermenorrhea or polymenorrhea occurred in 18 cases, in eleven of which there were uterine fibroids. In 7 the disturbance was functional. Testosterone propionate pellet implantation proved of value in ameliorating this disturbance in the functional group and in all but 2 of the group with uterine fibroids. Of these 2, 1 was temporarily alleviated and in the other the pellets sloughed out shortly after implantation.

UTERINE FIBROIDS WITHOUT MENSTRUAL DISTURBANCES BUT WITH PELVIC DISCOMFORT OR DEBILITY

Pellets of testosterone propionate were implanted in 7 patients because of massive uterine fibroids. These patients were anemic and complained of pelvic discomfort, general weakness and pressure symptoms. As a rule, following pellet implantation these patients felt stronger, pelvic discomfort was lessened and the anemia showed some improvement. Within a few months many of the patients with uterine fibroids in this and the other groups volunteered the fact that they were certain

Fig 7—Influence of implanted pellets of testosterone propionate on 8 patients with functional menometrorrhagia.

MENOPAUSE

Eight women in this series had pellets of testosterone propionate implanted for the amelioration of the menopausal syndrome (table 2). It was found that the best results were obtained with large doses, and the patient who responded most satisfactorily was one in whom four 100 mg pellets had been implanted (case 8). This patient had been treated with estrogens for some fifteen months with satisfactory though transitory results requiring continuous therapy. Another patient (case 5) required 5 mg of estradiol dipropionate parenterally every two weeks to keep her free from the hot flashes that kept her awake at night. With the implantation of two 200 mg pellets of testosterone propionate she has remained reasonably free from her menopausal syndrome for the seven months since their implantation.

DYSMENORRHEA

Nine women with functional dysmenorrhea were selected for pellet implantation because of the severity of their symptoms. On each patient various therapeutic procedures had been tried with disappointing results. Physicians had suggested hysterectomy or presacral nerve resection to 5 of these patients. The patients

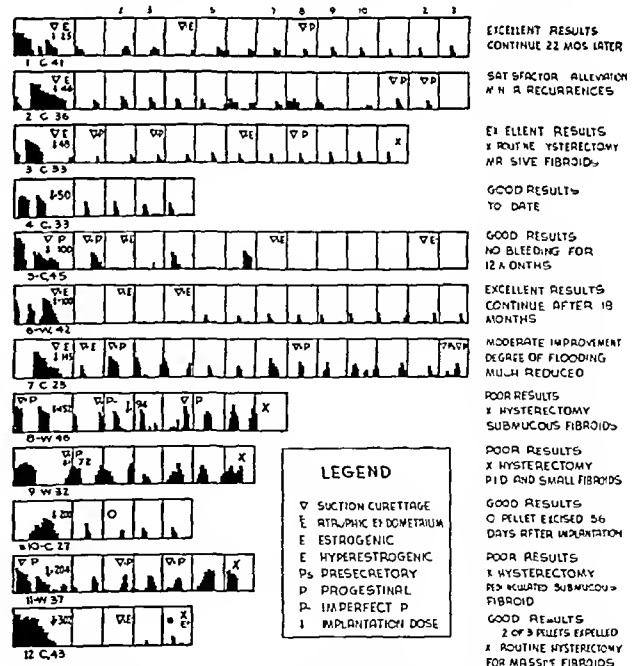

Fig 8—Influence of implanted pellets of testosterone propionate on menorrhagia associated with fibromyomas in 12 cases.

ranged in age from 19 to 38 years and the dose of the pellets implanted in each varied from 150 to 400 mg. No decided disturbance in the regularity of the cycles occurred in spite of the fact that two 200 mg pellets were implanted at one time in 5 of the patients in this group. In 1 patient extrusion of the pellets occurred thirty-six days after three pellets totaling 200 mg had

been implanted. She experienced satisfactory alleviation of pain during the menses while the pellets remained in situ, and only that period was included in the statistical data. Of the observations noted on forty consecutive cycles it was found that 75 per cent relief or better was obtained in 48 per cent of the cycles and approximately 50 per cent relief followed in 27 per cent of the cycles. Results were unsatisfactory in 25 per cent of the cycles. In another group of 14 patients whose dysmenorrhea was not primary or functional but associated with uterine fibroids, the results appeared to be better. These patients were observed from eight to twenty-two months, a much longer period than for the group with functional dysmenorrhea. In 11 patients the pain was considerably ameliorated. In several there were recurrences after variable lengths of time coincident with absorption of the greater part of the implanted pellet.

INFLUENCE OF TESTOSTERONE PROPIONATE PELLET IMPLANTATION ON NOCTURIA

In the group of women under consideration it was noted that many of them had coincidental disorders of micturition to which no pathologic basis could be ascribed. Thirty women had uterine fibromyomas and

sexual desire. On the other hand, restoration of the libido readily occurred following implantation in those women who at some time had known libido. Many married women volunteered the information that their loss of sexual desire led to marital discord. Following pellet implantation there was a return of coital pleasure which often terminated in orgasm. A reawakened interest on the part of the husband usually followed and husband and wife once more fell in love. Among those women who had a strong to moderate degree of sexual desire before implantation, all noted either no significant change or further increase in sexual pleasure. Two women with normal libido had a temporary decrease in sexual desire for several weeks immediately after pellet implantation and then a resurgence of the libido to a greater degree than that before the implantation. In several instances it was noted that the libido returned to the preimplantation status by the end of the third to the eighth month. In the majority, however, it persisted long after the pellets had been absorbed.

BLOOD CHEMISTRY STUDIES

Before pellet implantation and at various intervals afterward blood samples were taken and quantitative analyses were made of the following components. Non-

in 19 instances nocturia of two to ten times a night was present. Frequently diurnal frequency and dysuria were associated with the nocturia. After pellet implantation there was partial to complete amelioration of this syndrome. Because of this observation it is felt that the belief perpetuated in textbooks and in teaching may well be fallacious—that nocturia associated with uterine fibromyomas is due to pressure on the bladder.

In another group of 10 women with stigmas of endocrine imbalance, such as functional menorrhagia (5 cases), the menopause (4 cases) and dysmenorrhea (1 case), there was a similar syndrome of nocturia with or without diurnal frequency or dysuria. Routine urinary findings were negative or of little significance. The syndrome was partially or wholly alleviated following pellet implantation. Of the remaining 34 patients in this series without urinary disturbances, nocturia developed in 2 following pellet implantation (fig. 9).

LIBIDO

Information as to the status of the sexual libido before and after implantation was obtained from 54 women. The patients were classified as follows: (a) 8 women who never had any libido or had very little of it, (b) 22 women who had once known libido but lost it, (c) 14 women who had a moderate amount of libido, and (d) 10 women in whom libido was good or very good.

It was impossible to increase the libido of 2 psychologically frigid women who never had experienced

protein nitrogen, sugar, uric acid, creatinine, sodium, potassium and calcium. Although the values obtained fluctuated for each individual sample from the same patient and from different patients, there was no decided deviation from the normal fluctuations. The clinical picture observed before and after implantation of testosterone propionate pellets cannot be ascribed to any disturbance of those constituents of the blood that were studied, since the blood analyses showed them to be within the limits of normal values. On the other hand, Albright¹⁰ has shown that testosterone propionate is capable of restoring and maintaining a positive nitrogen balance, and promoting phosphorus and some calcium retention.

ENDOMETRIAL STUDIES

In 39 cases of this series endometrial biopsies were available for study. In the larger number of these there had been at least one biopsy made before pellet implantation and from one to seven afterward. After pellet implantation biopsies were usually done on the first day of the menses and as close to the expected onset of menses as possible. Occasionally biopsies were done in midcycle or during an amenorrheic episode to study the effect if any, of the implanted pellet on the endometrium. The biopsy specimens were stained routinely with hematoxylin and eosin, and frequently alcohol fixed tissue was subjected to Best's carmine stain and rechecked by the iodine reaction for glycogen.

¹⁰ Albright, Fuller, Parson, Williams and Bloomberg. Esther. Ther. apy. in Cushing's Syndrome. J. Clin. Endocrinol. 1: 375 (May) 1941.

An analysis of the histologic studies of these biopsy specimens permits of an answer to the obvious query: What is the effect of implantation of testosterone propionate pellets on the endometrium of the adult woman? In general implantation of pellets in doses up to 400 mg of testosterone propionate does not interfere with development of progesterational endometrium in the woman with a normal cycle. Moreover in some cases pellet implantation enhanced the development of a more mature progesterational endometrium in the women who had previously bled from an imperfect progesterational endometrium.

On the other hand, it appeared that testosterone propionate in doses used in this study was capable of maintaining the endometrium in the status attained before the implantation. For instance, cystic glandular hyperplasia or a persistent estrogenic endometrium was maintained in the majority of cases for many months after pellet implantation. It might be argued that such a finding is proof of the ineffectiveness of the hormone. The clinical improvement of the patient precludes such a conclusion. Furthermore, in many instances the anovulatory bleeding episodes were stabilized and bleeding recurred cyclically from a progesterational endometrium. In only 1 case, and that in a woman aged 45, did suppression of ovarian function occur as reflected in the endometrial pattern. This incident may have been in consonance with the hypophysial gonadal relationship expected at or near the menopause. The continuous and gradual absorption of androgenic substances from the testosterone propionate pellets implanted in doses up to 400 mg does not inhibit the rhythm of hypophysial activity. Fresh corpora lutea were often observed in patients submitted to laparotomy (hysterectomy) several months after pellet implantation. Furthermore, interference with glycogen deposition in the secretory endometrial glands was not found.

VAGINAL SMEARS AND VAGINAL MUCOSA

Routine vaginal smears were taken before implantation and at frequent but irregular intervals after implantation. The smears were stained routinely by carbol fuchsin and occasionally by the Shorr technic. The vaginal pH was determined by the use of nitrazine paper and a routine study of the vaginal secretions was made in search of monilia or trichomonads. Vaginal biopsy specimens were taken in many cases before implantation and at various intervals after implantation. In general, pellet implantation in the dosages employed did not interfere with the deposition of glycogen in superficial layers of the vaginal mucous membrane in those with functional ovaries (fig 10). Occasionally temporary regression of the vaginal mucosa exhibiting castration effects (fig 11A) were noted soon after implantation, but maturation toward normal (fig 11B) soon followed. In castrate or menopausal patients with moderately mature vaginal smears, pellets of testosterone propionate in small or moderate doses did not suppress or enhance the maturation of the vaginal epithelium. In 2 menopausal patients with castrate smears in whom larger doses (400 mg) were employed it was noted that testosterone propionate had an estrogenic effect, maintaining on the average a 3 plus reaction. In the menopausal cases with castrate smears similar estrogenic effects were not observed when smaller doses were employed.

ARRHENOMIMETIC PHENOMENA

Arrhenomimetic phenomena were not observed in any patient in this series. Particular attention was given to the patients as to changes in voice, hirsuties and enlargement of the clitoris. In spite of the fact that some patients had a moderate degree of masculine crimes before implantation no further exaggeration of hairy distribution was noted following pellet implantation. Many patients felt that their voices were stronger and sang with more resonance. Definite lowering of the pitch or persistent hoarseness was not observed. Slight hypertrophy of the clitoris was noted in but few patients and in none was there pathologic enlargement.

MISCELLANEOUS OBSERVATIONS

In general, patients experienced a sense of well-being and increased strength. They did not fatigue as easily. Appetites were better. In patients under observation

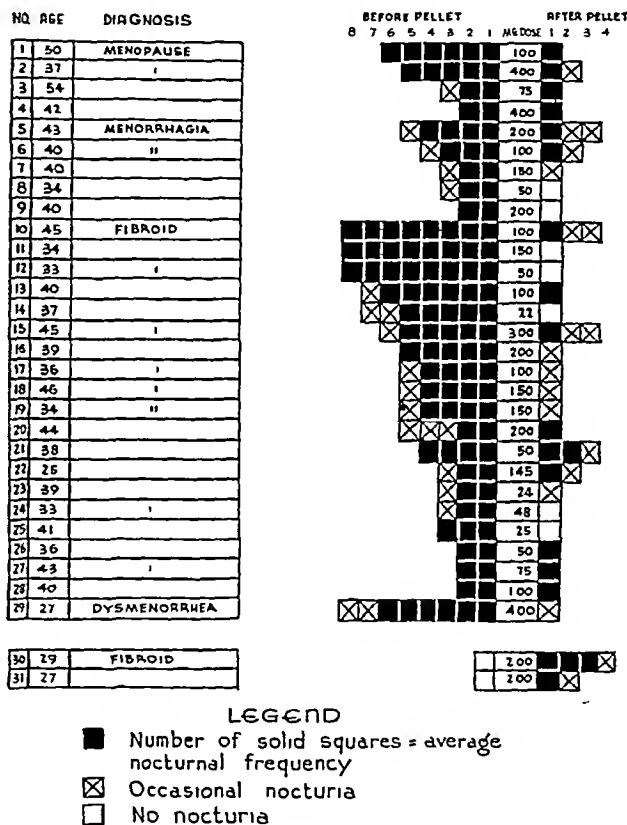

Fig 9—Influence of implanted pellets of testosterone propionate on nocturia

from four to twenty-two months an increase in weight of 1 to 20 pounds (453 Gm to 91 Kg) was noted. Blood pressure values remained stationary. Some of the patients with menstrual migraine noted diminution in the frequency and severity of attacks. Premenstrual tension was diminished when a smaller dose (150 mg or less) was used but was noted occasionally with larger dosage. Patients with premenstrual mastalgia and lumpiness of the breast obtained relief in all but a few instances. Nausea and vomiting associated with severe functional dysmenorrhea was arrested. Dyspareunia due to dryness of the vagina was partially alleviated because of increased mucoid vaginal secretions following pellet implantation. Pain or induration at the site of implantation occurred when in some instances one

or more of the implanted pellets were extruded from their subfascial locus and were harbored in the subcutaneous fat

COMMENT

There is no way to study human physiology other than to study human beings. Present concepts of the physiologic role played by androgens are based on the antigynecogenic responses obtained through the employment of massive and probably unphysiologic doses. The voices that have been raised against the use of androgens in female patients result from the concept that gonadal hormones should be sex specific, as well as on the observation that defeminizing and "ovarian-negating" effects are produced by androgens following massive parenteral doses. The parenteral use of massive doses of testosterone propionate in the female is contraphysiologic and "ovarian negating", however, the use of comparatively large doses of estrogens is also "ovarian negating". It must be recognized that in many aberrations of gynecic function the therapeutic effectiveness of androgens cannot be matched by the employment of estrogens. Moreover, some women respond unfavorably to estrogenic therapy. Estrogens may produce severe nervous tension states, uterine bleeding, breast pain, abdominal bloating and pelvic discomfort. In such cases androgens frequently yield gratifying results without undesirable side reactions.

Since it has been shown by Deansley and Parkes that the implantation of hard pellets permits of a continuous and prolonged hence nearly physiologic action of the fat soluble hormones, it was felt that the action of androgens in female therapy might best be studied by the subfascial implantation of pellets of testosterone propionate. In this way more nearly physiologic doses of androgens would be employed and some of the complex biologic properties of testosterone propionate might be clarified. Since arrhenomimetic phenomena were not observed in any one of the 64 patients in this series by the use of subfascial implantation of testosterone propionate pellets in doses varying from 22 to 400 mg., a reconsideration of the physiologic properties of testosterone propionate thus employed might be in order.

The doses used in this therapeutic venture were at first and perhaps still are empiric. In March 1941 we recommended implantation of pellets in doses from 22 to 145 mg. of testosterone propionate for the palliative therapy of uterine bleeding associated with fibromyomas.¹⁰ The doses were gradually increased to insure therapeutic effectiveness in patients with dysmenorrhea and menopausal syndrome. Virilism was not observed with doses up to 400 mg. Larger doses were not used, since Loeser¹⁰ had implanted with therapeutic effectiveness testosterone and testosterone propionate pellets in doses of 600 to 1,650 mg. but observed transitory signs of masculinization in every one of 8 patients in his series. Geist¹¹ implanted pellets containing from 150 to 500 mg. of testosterone propionate subcutaneously in 9 cases (8 with functional bleeding and 1 with menopausal syndrome) and reported in February 1941 that he found no therapeutic effect or evidence of effective absorption. It is difficult to reconcile this observation with a later opinion expressed in June 1941 by Geist and Salmon³ that androgens administered by subcutaneous pellet implantation in doses of 50 to

675 mg. were now believed to be therapeutically effective but that arrhenomimetic symptoms followed after a few weeks. Abarbanel¹² and Geschlechter¹³ have used testosterone propionate pellets in much smaller doses with satisfactory results.

An evaluation of my results indicates that testosterone propionate pellet implantation is capable of alleviating many aberrations of gynecic function without suppression of hypophyseal gonadotropic function or interference (antagonism) with the action of endogenous estrogen or progesterone on the uterus and vaginal mucosa. Ovulation and cyclic maturation with glycogen deposition of both the secretory endometrium and the vaginal mucosa was not interfered with. Experimentally, Hartman¹⁴ made similar observations on the endometrium of the monkey. In menorrhorrhagia the therapeutic results cannot definitely be ascribed to the influence on the hypophysis or the ovary, since the endometrial pattern which reflects hypophyseal gonadal relationship was frequently maintained in the status it had attained before implantation. Excessive bleeding was arrested in spite of the persistence, for instance, of the cystic glandular hyperplasia.

Since morphologic regression in the endometrium in general was not attained the therapeutic effect of testosterone propionate may be achieved through its inhibitory action on the vascular and muscular factors involved in menstruation.⁵ Because of the observation that uterine fibroids decreased somewhat in size, a myotrophic property perhaps may be attributed to testosterone propionate. In this respect it is of interest to recall the work of Lipschutz and Vargas,¹⁵ who were able to offset the fibromatogenic effect of estrogens in the guinea pig by androgens. Abarbanel¹² attributed the therapeutic effect of testosterone propionate in menorrhagia to the sum total of the twofold effects of testosterone propionate, i. e. inhibition of intermittent uterine contractions and direct stimulation (constricting) action on myometrial elements.

The relative though temporary effectiveness of implanted testosterone propionate pellets in menopausal patients is difficult to explain. The action cannot be due to inhibition of the pituitary activity, since in women with a normal cycle the rhythm was not disturbed even with doses up to 400 mg. The action may be due to estromimetic properties of testosterone propionate. Salmon³ has attributed such properties to testosterone propionate when used in sufficient dosage, since castrate vaginal smears were converted to normal. This was confirmed by our studies. It was found that testosterone propionate in 400 mg. doses satisfactorily relieved the menopausal syndrome and in 2 patients prevented atrophic changes of the vaginal mucosa. However, when smaller doses were used the therapeutic effectiveness was less and of shorter duration and did not suppress vaginal maturation or prevent vaginal atrophy. Silberman and his associates¹⁶ found

that the subcutaneous implantation of pellets of testosterone propionate in doses of 25 mg was the most satisfactory method of treating the menopausal patient.

In dysmenorrhea the action of testosterone propionate by pellet implantation can be only speculative at this time. The action, when therapeutically effective, may be due to a modification of uterine contractions. Both Robson¹⁷ and Leonard¹⁸ have shown that testosterone propionate suppresses uterine contractions in the rabbit. The anesthetic properties of certain steroids such as testosterone propionate have been stressed recently by Selye¹⁹ and may account for some of the results obtained in dysmenorrhea, menorrhagia, pelvic discomfort and mastalgia.

The alleviation of the syndrome of nocturnal frequency in these patients was due to some specific action of the implanted steroid and cannot be attributed to the minor decrease in size of the tumors which frequently occurred.²⁰ There are many indications that the genitourinary tract is under hormonal influence. This may be adduced from the following facts: 1 One of the first symptoms associated with early pregnancy is a disorder of micturition. 2 In pregnancy, hypertrophy and dilatation of the ureters and other genitourinary disturbances may occur. 3 In the climacteric, urinary frequency, urgency and incontinence are common accompaniments of the menopausal syndrome. Mocquot and Moricard²¹ were the first to employ compounds of testosterone for the alleviation of disorders of micturition in menopausal patients. Recently, Salmon and his associates²² were able to keep menopausal patients with disorders of micturition symptom free by large doses of estrogenic hormone. These patients appeared refractory to orthodox treatment. 4 Experimental data prove that certain components of the genitourinary tract are under hormonal influence. Castration of the male rat is followed by a decrease in weight of the kidneys. This reduction in weight can be prevented by the administration of chemically pure androgenic substances. Selye²³ believed that testosterone exerts a specific action on kidney tubules. Korenchevsky²⁴ has claimed that androgens are nephrotrophic, causing an increase in the weight of kidneys and in the size of tubules in both normal and castrate female rats.

Libido is a highly complex function in which psychologic, anatomic, neurologic, sentimental and hormonal components play important roles. The role of the hormonal component has not received due attention.²⁵ The increase in libido in the female following the administration of chemically pure androgenic substance

in one form or another must be the result of a specific pharmacologic effect. Libido may be spoken of as a phenomenon depending on well defined chemical substances. The action may be mediated through minor changes in electrolyte balance or the effect may be directly on specific organs. In some patients frigidity was due to dyspareunia because of dryness of the vagina. Following testosterone propionate pellet implantation libido returned and increased mucification of the vaginal epithelium was noted with resultant improvement in sexual relations. Hartman¹⁴ noted that the action of testosterone on the sex skin of the female monkey invariably was estrogenic. The sex skin was always brilliant red.

CONCLUSION

It appears that the pellet method of implantation has more nearly approached the endogenous mechanism of hormone secretion in the normal female organism. It is entirely rational to suppose that the exogenous administration of male hormone in this manner adequately and satisfactorily restored the normal ratio of androgenic and gynecogenic hormones. Clinical manifestations of disruption of this ratio were corrected without the untoward effects observed after administration of unphysiologic doses of androgenic substances by parenteral means.

ABSTRACT OF DISCUSSION

DR WILLARD M ALLEN, St Louis Excessive bleeding which occurs from the uterus during the menstrual period in some women with a myomatous uterus or in patients with functional bleeding has been variously explained, but any explanation must consider the condition of the blood vessels. The reduction of bleeding which Dr Greenblatt has observed following the use of testosterone propionate must therefore be explained by some effect on the uterine vessels. One of the outstanding effects of estrogens is increased cyanosis and congestion of the uterus. Androgens are known to inhibit many of the effects of estrogens. I assume, therefore, that the reduction of bleeding was brought about by inhibition of the effect of estrogens on the vessels of the uterus. This is in accord with Dr Greenblatt's observation that myomas have decreased in size while the patient is under the influence of testosterone. The question which arises is whether this effect is a direct inhibitory action of the normal effect of estrogen or whether the supposed change is due to an actual diminution in the amount of estrogen produced by the ovary. Testosterone does affect the anterior lobe of the pituitary and thus indirectly leads to ovarian atrophy. This is not likely to be the explanation of his results, since many of his patients had essentially normal cycles afterward. We all know that when the ovary is unduly inhibited the menstrual cycle is liable to be affected. Dr Greenblatt has observed, I believe, that most of the patients getting testosterone had a considerable increase in libido. I think we are inclined to believe that estrogen is responsible for such sexual desire in the female, and, conversely, that androgen is the motivating agent in the male. This is not entirely correct. In some mammals progesterone is a much better agent for the induction of sexual receptivity than is estrogen. Mating, for instance, can be induced with regularity in castrated female rats and guinea pigs which have been primed with estrogen by a single injection of progesterone. The increased libido in these women under the influence of androgen may, in fact, be directly due to changes in the clitoris and the vulvar region brought about by the use of testosterone. We know that if large doses of testosterone are given there is hypertrophy of the clitoris.

DR UDALL J SALMON, New York Androgen therapy has been a major interest of mine for the last six years. As regards the value of androgen therapy in gynecology, there is a divergence of opinion. The group with which I am associated at the

Mount Sinai Hospital feels that androgen therapy has a sound rationale based on experimental studies in women and supported by a wide clinical experience. Last year, before this section in Cleveland, Dr Geist and I presented our experience with androgen therapy in a variety of gynecologic disorders. The series of cases totaled over 400, the period of observation varying from six months to more than four years. That series included a group of 40 cases in which testosterone and testosterone propionate were implanted both in the form of loose crystals and in the form of pellets, varying in dosage from 50 mg to 675 mg. Our studies revealed that, if one administers more than 500 mg of testosterone propionate to women during the course of one cycle, certain striking biologic effects result. The hypophysis is inhibited, ovulation fails to occur, estrogen and progesterone formation is suppressed, and, as a result of that, involutional (estrogen deficiency) changes occur in the endometrium and in the vagina. The threshold for these effects is about 500 mg. It is also, incidentally, the threshold for the induction of the virilization symptoms. Fortunately the hormone is clinically effective in much smaller doses, so that it is possible to exploit the therapeutic properties of this hormone in the female without risking the danger of inducing any of these virilization phenomena. One aspect of androgen therapy that Dr Greenblatt did not have time to elaborate was the effect of androgen on libido. Dr Geist and I have completed a study on the effects of testosterone propionate on the sexual reactions of women. Our observations led to the following conclusions: Androgens (a) cause a heightened susceptibility to psychic and somatic sexual stimulation, (b) produce an increased sensitivity of the external genitalia and (c) induce a greater intensity of sexual gratification. This property of the androgens is, however, not an unadulterated virtue, since if administered in excess to women with normal libido it may cause abnormal intensification of desire and may lead to marital complications. Our experience with the implantation of androgens has not been as satisfactory as Dr Greenblatt's. In a few instances, chiefly cases of premenopausal menometrorrhagia, we have had good therapeutic results, but in the majority the implantations were either ineffective or produced hypertrichosis or acne, necessitating excision of the pellets. Administration of androgens by implantations we feel, unnecessarily complicates the procedure of androgen therapy without offering any advantages over the intramuscular or oral methods.

DR L. F. HAWKINSON, Oakland, Calif. In 1935 I pointed out that the menopausal syndrome was usually much more severe in patients who had hysterectomy or intrauterine radium. These patients often require five times the dose of estrogen to control the symptoms. The uterus probably plays a very important role in the maintenance of ovarian function. Although I have used few testosterone pellets in the female, in those patients in whom pellets were used the results were very satisfactory. For the past four years I have used testosterone propionate by hypodermic injection in the female and have never seen any virilism or effects that might be considered harmful. I have adopted a regimen in menopausal women who have menometrorrhagia, particularly those who have a tendency to bleed profusely when given estrogens. This regimen alternates estrogens with androgens. Two thousand rat units or 10,000 international units is given for two or three doses and then a dose of 10 or 25 mg of testosterone propionate. The ratio between the estrogens and androgen is balanced so that the bleeding is controlled. The frequency of the dose of androgen is increased if the bleeding persists. In regard to libido, I find that the majority of patients who receive sufficient amounts of testosterone notice an increase in libido. The alleviation of menopausal symptoms by androgen alone requires large doses. A combination of estrogen and androgen relieves both the symptoms and excessive bleeding.

DR CHARLES F. GESCHICKTER, Baltimore. I have been using pellet implantation for cancer cases for some years and have had a similar experience to that of Dr Greenblatt. I have never given more than 100 mg in the form of a pellet. Most of these patients receiving 20 mg pellets have been treated at intervals of one to two months for periods as long as three

years. I have never had any effects of virilism in these patients. The use of pellets is condemned by some. On scientific grounds I believe that it is certainly worth while in order to learn what is the role in therapy of the androgens, because experience in the laboratory teaches us that the hormone is about three times as efficient in the form of a pellet as it is by injection. Therefore, if we are to explore the field of androgen therapy, pellets properly used offer the hormone the most efficient chance to demonstrate what it can do. There are some words of caution. I think, that should be expressed when one discusses pellet therapy. I do not approve of the large pellets, which are more often extruded and, if not, will enable both the physician and the patient to take a three hundred day holiday. Particularly when one is treating myomas of the uterus or menorrhagia one must remember that bleeding from the uterus is a symptom of a great many conditions, and to mask it successfully with a form of pellet therapy and then to have that therapy last over a period of months is not without its danger. If one uses the smaller pellets one practically never gets extrusion. I do not have to use sutures, I never go down to the fascia, I do not have to use the operating room. A small wheal of procaine hydrochloride is used. I have never used more than 2.5 cc. of procaine. I use the bistoury scalpel and the mosquito forceps to spread. I try not to make the incision quite large enough, I make it small enough so that it has to be spread with the clamp in order to get the pellet in. I never put in a suture but seal with a strip of flamed adhesive plaster. Using that technique I have never had an extrusion or an infection. I think the pellet therapy could be made extremely simple and it certainly is the efficient way to find out what the hormone can do.

DR CARLOS A. P. LAMAR, Miami, Fla. I have used implantation of pellets of pure testosterone instead of testosterone propionate, with results that parallel those of Dr Greenblatt. The definite role of androgen in the treatment of excessive menstrual bleeding has been amply demonstrated. The implantation of pellets can be done without operative procedure as the previous discussor has said. That is the routine that I ordinarily use. I have been observing the effect on libido for some time. I have noticed that the increase in libido is much more pronounced in women near the menopausal age than in younger women. Some women in the early twenties have been treated with parenteral doses of testosterone propionate as high as 1,200 mg in one month without producing any symptoms of virilism and without increasing the libido. I have 2 of those cases at present.

DR ROBERT B. GREENBLATT, Augusta, Ga. I should like to say another word about libido since limitation of time did not afford the opportunity to say much in my paper. Libido is a complex phenomenon depending on physiologic, sentimental and anatomic factors. We have neglected the hormonal aspects. In fact, it might be said that love, marital harmony and libido are influenced by blood chemistry. One might be bold enough to suggest that libido is purely a chemical test tube equation but that would be going too far. Certainly libido may be increased in patients who have little or no libido and particularly in patients who once knew libido but have lost it. In this respect testosterone propionate probably has a specific pharmacologic action. In general I found that after pellet implantation the clitoris was not very much enlarged. However, when androgens were administered parenterally I found that enlargement of the clitoris was much more frequent. The amount of testosterone propionate that is made available to the organism by implantation of a 100 mg pellet is small, for I found the average absorption that takes place over a period of eight months' time is only 0.3 mg a day—a comparatively small amount. Mrs. Culminating effects were not observed in any of the patients. Limitation of time prevents me from discussing the problems raised by the various speakers who were kind enough to discuss my paper. However, I agree with Dr Geschickter that the technique can be improved. I recommend the method presented when large dosages are to be employed but when small amounts of hormones are to be administered I see no objection to using his method of subcutaneous implantation.

THE EVALUATION OF ANTISEPTICS

ALBERT C HUNTER, PH D

WASHINGTON, D C

The discovery or development of the "ideal" antiseptic is an objective much sought by research workers in the fields of bacteriology, chemotherapeutics and preventive medicine. Although this objective obviously has not yet been attained, it is apparent that diligent search continues for a chemical compound which has the characteristics of an ideal antiseptic, namely: high germicidal or inhibitory properties, no tissue toxicity or at most a very low toxicity, freedom from specificity, efficiency in the presence of organic matter, power to penetrate, stability and perhaps other characteristics, including low cost. Efforts to produce useful, if not ideal, antiseptics have resulted in offering to the medical profession and to the public a wide variety of chemical substances, including mercurials, phenolic compounds, silver preparations, products of the liquor antisepticus type, dyes, halogen compounds and many others with staggering organic chemical designations. Most of these preparations are offered for general antiseptic purposes, although in some cases there is recognition among the informed, but not always disclosed on the label, that the compounds are relatively specific in their action on certain bacterial groups. Some preparations claim to be and are, efficient germicides, others make no claim beyond the power to inhibit bacterial growth. A few preparations are offered for the "sterilization" of surgical and dental instruments. Substances proposed for the prevention and cure of certain mycotic infections are not uncommon.

The task of appraising the merits and demerits of such a group of substances with diverse properties becomes one of increasing magnitude and one possessing grievous obstacles to satisfactory evaluations by both the laboratory worker and the clinician. A review of the literature reveals a tendency to attempt to develop one universally applicable *in vitro* test, standardized in all of its details and yet with all its niceties, set up under conditions not in any way resembling those under which the antiseptic is expected to function in actual practice. In contrast to the investigator who chooses to evaluate solely on the basis of the laboratory test is the person who scorns *in vitro* procedures in their entirety and sees merit only in clinical results. Appraisals arrived at completely from clinical practice may too often be based on the acceptance of empirical observations as valid evidence of antiseptic efficacy without due consideration to all the uncontrolled factors.

United States Department of Agriculture circular 198¹ has often been cited as the source of a "standard" or "official" method favorable response to which classes a substance as efficacious for the purpose recommended and consequently demonstrates its compliance with the requirements of the law. To the extent that the circular described procedures as those adopted by the Food and Drug Administration and suggested tests that could be applied to specific types of preparations, some justification has probably existed for such an opinion. However, this was not the intent of the document and is not a proper interpretation of its con-

tents. Much has been written² to point out the fallacy of applying phenol coefficients to antiseptics as differentiated from disinfectants directly comparable with phenol. The so-called F D A test utilizing *Staphylococcus aureus* as the test organism at its best provides information concerning the ability of the compound tested to destroy staphylococci only under the conditions of the test. Furthermore, Brewer³ has called attention to the faulty interpretations which may follow too great dependence on *Staph. aureus* as a test organism for all types of preparations, some of which may be intended for the destruction of organisms of entirely different resistance. The F D A test, the agar-plate tests and the wet filter-paper and dry filter-paper tests described in circular 198, within their limitations, serve a useful purpose. However, rather than to accept the results of any of these procedures as a sufficient measure of efficacy a more logical approach to the job of appraisal appears to lie in a broader concept of evaluation, which because of its difficulties of application has not been universally adopted, even though its principles have from time to time been outlined by those who specialize in this field.⁴ To quote Browning "Antiseptics intended for therapeutic use must not be considered *en bloc* or selected solely on the basis of their ability to kill rapidly some test organism *in vitro*. Each must be examined as regards selective action on various bacteria in protein as well as watery media *in vitro*, and as regards effects on tissues *in vivo*. Such tests give valuable indications, but the chemotherapeutic efficacy of a substance is finally determined by its influence on the pathogenic action of organisms in an infected host." This point of view, entirely sound in its expression, admits the impracticability of reaching a conclusion as to true efficacy from the results of a single *in vitro* test. The problem then becomes one of fitting together the results of old established procedures with clinical observations and with the results of additional tests, some recently developed and some not yet conceived, to form a complete picture of the properties of a substance under scrutiny.

In determining whether or not a product represented as an antiseptic meets the requirements of the Federal Food, Drug and Cosmetic Act of 1938⁵ the question of efficacy under conditions of use becomes a matter of paramount importance. All articles intended for use in the diagnosis, cure, mitigation, treatment or prevention of disease in man or other animals are classed as drugs within the meaning of that act and if shipped or offered for shipment in interstate commerce must comply with the provisions of the statute. Section 201(o) of the act states "The representation of a drug, in its labeling, as an antiseptic shall be considered to be a representation that it is a germicide, except in the case of a drug purporting to be, or represented as, an antiseptic for inhibitory use as a wet dressing, ointment, dusting powder, or such other use as involves prolonged contact with the body." It is then pertinent to give heed to the requirement of 502(f), which defines a drug as misbranded unless its labeling bears adequate directions for use. Furthermore, 201(n) of the law provides that

"in determining whether the labeling is misleading there shall be taken into account (among other things) not only representations made or suggested but also the extent to which the labeling fails to reveal facts material in the light of such representations."

A self-imposed standard of performance is thus set up for each product by its labeling claims. Failure to function in conformity with those claims renders a product adulterated or misbranded within the meaning of the act.

In evaluating the efficacy of preparations in the light of these legal requirements the single *in vitro* test may be applicable to one class of products, namely those which fail to exhibit any inherent germicidal or bacteriostatic properties even under the most favorable laboratory conditions. Obviously they are without value and need not be tested further.

Dissatisfaction with the old procedures is apparent from the contributions to the bacteriologic and medical literature made in the past decade, proposing methods designed to provide information to facilitate evaluation of antiseptics under conditions of use. Browning,⁶ Hunt,⁶ Kempf and Nungester,⁷ and Sarber,⁸ among others, have proposed *in vivo* methods. In some of the proposed methods lesions on laboratory animals are produced and treated *in situ*, while in others the animal is used as a culturing medium to test the pathogenicity of the test organisms surviving treatment with the antiseptic on or within the infected host. The method of Price⁹ involving the examination of skin washings following treatment has received attention. Animal tests of the type proposed have been generally subject to criticism based on the variability of the individual and on the lack of control possible over all elements of the test. Regardless of the validity of the criticisms in specific cases, merit must be ascribed to any reasonable *in vivo* procedure on the theory that such tests provide some information concerning performance of an antiseptic in the presence of living tissue and contribute some evidence to supplement that obtained by other procedures.

Notable among the advances made in this field are those methods designed to determine the toxic effect of antiseptics on tissue as contrasted with their effect as germicides. While essentially *in vitro* tests, these methods depart radically from the strictly cultural procedures and provide valuable data to throw light on reactions that may be expected under conditions of body use. In 1935 Salle and Lazarus¹⁰ proposed a method of evaluation based on a comparison of the resistance of bacteria and embryonic chick heart tissue to germicidal substances. By dividing the highest dilution of an antiseptic required to prevent growth of embryonic tissue embedded in plasma diluted with Tyrode's solution by the highest dilution required to kill the test organism, Salle and his associates¹¹ computed toxicity

indexes for a number of well known substances used as antiseptics. From their tests they concluded that in general the simple inorganic substances rated higher than the newer and more complex compounds. The factor of tissue toxicity in the evaluation of antiseptics was also discussed by Nye,¹² who gave consideration to the harmful effects of antiseptics on white blood corpuscles. In reports¹³ dealing with the toxicity of antiseptics, Welch and his associates, after describing a method for determining the effect of chemical antiseptics on phagocytosis, explained the mechanism of the toxic action of germicides on whole blood by stating that impairment of the phagocytic function of the leukocytes is a primary effect exerted by the antiseptic against the humoral, in contrast to the cellular, elements of the blood. In pursuing toxicity tests based on determination of the loss of activity or actual destruction of the leukocyte, recognition is granted to the part normally played by such cells in protection against invading organisms. It is reasonable to conclude that a substance used as an antiseptic should augment rather than interfere with the activity of these cells and that any compound strikingly more toxic for leukocytes than for bacteria should thereby acquire demerits as an antiseptic. Applying the toxicity test using whole blood as a tissue, Welch, with others, reported the toxicity indexes of a number of antiseptic substances, including preparations containing soap and alcohol particular attention being directed to mouthwashes.¹⁴ Of eighty-seven mouthwashes tested sixty-two in 1:5 dilution exerted a toxic effect on blood as measured by impairment of phagocytosis, the remainder were toxic in higher dilutions. By comparison with their power to function as germicides in the presence of whole blood toxicity indexes greater than 2 were determined in every instance. The authors of the report referred to frankly recognize the impossibility of evaluating antiseptics for all their uses by application of the toxicity test alone. On the other hand they do point out the value of data derived from that test in supplementing other data to arrive at a proper appraisal of an antiseptic.

Bronfenbrenner, Hershey and Doubly¹⁵ also utilize tissue in a procedure proposed as helpful in the evaluation of germicides. By their method the concentration of disinfectant necessary to cause 50 per cent reduction in the rate of oxygen uptake by mouse liver cells in saline suspension is determined and is compared with the concentration causing 50 per cent inhibition of the rate of oxygen consumption by a suspension of *Escherichia coli*. The authors report that data for tissue toxicity obtained with several disinfectants are in satisfactory agreement with values obtained by intraperitoneal injection into the mouse.

Perhaps in some of their aspects the newer tests do not lend themselves to the rigid "standardization" of

the phenol coefficient procedure. However, it is not unreasonable to permit some relaxation on that point. In actual practice the user of antiseptics is not confronted with standard subjects for treatment nor is the infectious agent to be combated a standard factor. It may be suggested that in searching to learn the true merits of an antiseptic under conditions of use some of the niceties of standardized procedure might profitably be sacrificed.

Between the laboratory test and the results to be obtained in practice exists a gap which should be bridged by clinical observations and practical experience. If the laboratory studies are to be useful to the practitioner, they must be interpretable in terms of actual use. It is pertinent to point out the fallacy, for instance, of accepting as evidence of their efficacy as sterilizers of surgical and dental instruments chemical preparations which have been tested in the laboratory only against vegetative forms of bacteria. Reviews of that subject by Knighton¹⁶ and Brewer¹⁷ have thoroughly discussed the ineligibility of preparations to the designation of "sterilizer" until it has been proved that they are efficacious in the destruction of resistant bacterial spores. With respect to antiseptics for use on the body, if the laboratory tests for their evaluation do not take into consideration tissue toxicity and the interfering factors present in the living host, and not in the test tube, the conclusions drawn may be quite misleading. Speaking for the government agency charged with the enforcement of the Food, Drug and Cosmetic Act, there is no single "standard" or "official" test for the evaluation of antiseptics. The objective in testing a preparation claimed to be an antiseptic with prescribed directions for use is the collection of related parts of a picture to show not only the inherent germicidal or inhibitory properties of the compound but the degree of efficacy with which these properties are applied under the conditions of use.

ABSTRACT OF DISCUSSION

DR WARD J. MACNEAL, New York. In evaluating antiseptic and germicidal agents a distinction should be drawn between three groups of these agents: (1) those acting at a distance from the human host, (2) those acting on epithelial surfaces or on superficial wounds and (3) those designed to act after absorption into the circulating fluids. These may be designated respectively as (1) disinfectants, (2) antiseptics in the narrower sense and (3) anti-infectious therapeutic agents, chemical and biologic. There is no single easy and simple method of evaluating all these agents. For those acting at a distance the harmful property may be wholly vitiated before reaching the host. An agent to be used for quick action on a body surface should be effective against the germs and should not be dangerously toxic in the amounts absorbed. Local tissue toxicity, which has been featured by Fleming and also by Welch and Hunter in previous papers, seems to have been too greatly stressed by these authors. As Professor Garrod has said, the local destruction of tissue is a small price to pay in consideration of the control of the infectious agent. Remote toxicity after absorption is of greater moment, as for example in the nervous system after alcohol or sulfamethylthiazole, in the myocardium after sulfonamides in general, in the liver after arsenicals, in the kidneys after mercurials. Direct experimental tests on animals would seem most logical. Such tests present difficulties, and not all microbes are adapted to such examination. All kinds of *in vitro* tests should be welcomed. We need to be on guard against accepting a

tricky result obtained by some special procedure designed to extol or to condemn some particular agent. By omitting the well known step of inactivation, one may exaggerate the apparent germicidal action of iodine, and by testing alcohol or liquor antisepticus in too dilute form one may easily cast discredit on their germicidal value. Errors of this sort were current thirty years ago but should hardly be expected at present. Infectious agents are many in nature, and one drug may not be effective against all. It has recently been shown that viruses of vaccinia and influenza are quickly inactivated by liquor antisepticus although relatively resistant to some other antiseptics. I would plead, therefore, for a broadminded approach which welcomes all obtainable information about the properties of any antimicrobial agent.

DR ALBERT C. HUNTER, Washington, D. C. The first class of products that Dr. MacNeal mentioned is classified as disinfectants, since they are to be used on inanimate objects. I did not mean to include them in the paper at all. In our work we have an arbitrary division, because disinfectants for use on inanimate objects are subject to control by another law. When one says antiseptics one is thinking of drugs for use in or on the body. I agree with the statements Dr. MacNeal made about not applying the toxicity test to disinfectants. Furthermore, the toxicity test on antiseptics is not used as a universal test to the exclusion of all others. My point is that there is no universal test. What we propose to do is like the assembling of the pieces of a jigsaw puzzle. We determine the inherent killing and inhibitory powers in test tube culture and the tissue toxicity and obtain other pertinent data. If we put the pieces together and they make a good picture the product has merit accordingly. If it is a bad picture that is what we want to find out too. I should like to leave it clear that officially we are not presenting the toxicity test or any other single test as the sole measure of the efficacy of an antiseptic.

CIRCULATORY ADJUSTMENTS DURING HIGH SPINAL ANESTHESIA

E. M. PAPPER, M.D.

S. E. BRADLEY, M.D.

AND

E. A. ROVENSTINE, M.D.

NEW YORK

It is generally agreed among experienced surgeons and anesthesiologists that hypotension is a corollary of high spinal anesthesia. However, any discussion of the cause, the significance to the patient's welfare or the optimum treatment for the fall in blood pressure so regularly observed while operation is in progress during high spinal anesthesia would provoke many arguments. Theoretical discourses, data from laboratory experiments and clinical investigations of spinal anesthesia have multiplied with the years since the method was first advocated, and no small fraction of this accumulated literature is devoted to the problems concerned with the circulatory adjustments. Despite these efforts, the problems await solution and, notwithstanding the fact that a decided fall in blood pressure from whatever cause must be considered unphysiologic, this complication during spinal anesthesia has not been evaluated satisfactorily in terms of morbidity and mortality.

It is important to evaluate accurately the effects of spinal anesthesia on the circulation, since the procedure has such a prominent role in present day abdominal surgery. The flaccid relaxation of abdom-

anal muscles and the strong intestinal contractions produced by spinal anesthesia have a fascinating and legitimate appeal to many surgeons. Moreover, with the methods available for anesthesia there is no agreement among anesthetists as to the relative merits of spinal and inhalation anesthesia in the anesthetic control of the abdomen. In this discussion, therefore, the laboratory and clinical data which have been prominently displayed to determine and explain the factors concerned in the circulatory adjustments to spinal anesthesia will be briefly but critically reviewed. Additional clinical data are presented also, and their significance in surgery during high spinal anesthesia is suggested.

Among the theories advanced, and in most instances supported, by laboratory investigations as the pathogenesis of the fall in blood pressure during spinal anesthesia are (1) hematogenous intoxication, (2) direct action on the medulla, (3) paralysis of adrenal nerves with reduced secretion of epinephrine, (4) the anoxia theory, (5) paralysis of the vasoconstrictor fibers in the anterior spinal roots and (6) the theory of stagnation in the postarteriolar bed.

HEMATOGENOUS INTOXICATION

It was proposed that the rapid absorption into the blood stream of anesthetic drugs injected subdurally might precipitate the hypotensive effects observed.¹ This was held untenable when it was conclusively demonstrated that intravenous injections of such drugs do not produce the severe or protracted disturbances in circulation that occur after intraspinal injection.² The theory is without support at the present time.

DIRECT ACTION ON THE MEDULLA

The theory of direct action on the medulla presupposed that the vital centers in the brain stem are more sensitive to the anesthetic agent than are the nerve roots emanating from the spinal cord. There is substantial evidence that such is not the case.³

PARALYSIS OF ADRENAL NERVES WITH REDUCED SECRETION OF EPINEPHRINE

Since the adrenal glands derive their innervation from the celiac plexus and the splanchnic nerves, paralysis of these nerves during high spinal anesthesia might be expected to reduce the supply of epinephrine to the body and thus produce a fall in blood pressure.⁴ There are two objections to this thesis. First, Bazett⁵ and Durant⁶ point out that ligation of the adrenal veins or bilateral adrenalectomy is not accompanied by a fall in blood pressure. Second, Smith⁷ maintains that the administration of epinephrine to man causes considerable arteriolar dilatation and produces, if anything, a fall in diastolic pressure and a well maintained or increased systolic pressure. It is difficult to understand, therefore, how absence of the adrenal hormone could produce vasodilatation if the converse is true. This theory no longer enjoys any degree of popularity.

THE ANOXIA THEORY

The anoxia theory as promulgated by Gray and Parsons⁸ is based on observations on man and dogs that the blood pressure falls in proportion to the amount of intercostal muscle paralysis. Thus the circulatory changes are secondary to anoxia produced by decreased pulmonary ventilation. Seevers and Waters⁹ supported this theory and demonstrated the return of blood pressure to normal or above normal by the administration of oxygen during artificial respiration in animals anesthetized to the fifth thoracic vertebra or above.

The thesis of anoxia as the cause of hypotension in spinal anesthesia is subject to criticism on several counts. The correction of hypotension in dogs under high spinal anesthesia may be accomplished by change in position, as shown by Burststein,¹⁰ who noted the usual fall in blood pressure in the supine position in dogs whose subarachnoid space was continuously perfused with a 3 per cent solution of procaine hydrochloride and an immediate return to normal blood pressure by being placed in the right or left lateral position despite the maintenance of anesthesia to the cervical cord. It is thus quite probable that the fall in blood pressure noted in the experiments of Seevers and Waters may be due to the embarrassment of venous return by an increase of the aspiration of blood into the thorax during artificial respiration and passive massage of the vessels in the abdomen and chest. Since measurements of cardiac output were not made and artificial respiration without oxygen was not done the interpretation of these data is open to question and might profitably lend itself to further study.

Further objection to the anoxia theory is made because of the use of anesthetized and premedicated animals. These objections will be elaborated on more fully in a consideration of the theory of arteriolar dilatation.

PARALYSIS OF THE VASOCONSTRICTOR FIBERS IN THE ANTERIOR SPINAL ROOTS

The theory of vasoconstrictor paralysis in spinal anesthesia producing hypotension by arteriolar dilatation has among its adherents most investigators of spinal anesthesia. It is supported by Babcock,¹¹ Burch and Harrison,¹² Ferguson and North¹³ and many others. Because of the wide support of this thesis, which we do not accept, the evidence for the importance of tonic activity of the vasoconstrictor fibers in maintaining blood pressure must be examined critically.

The concept of vasotonic activity in the sympathetic nervous system in normal animals is based largely on the fact that the blood pressure falls or the peripheral blood flow increases immediately after surgical section of the splanchnic fibers in anesthetized cats and dogs. The major criticism of all this work and of the conclusions drawn is that observations were made in almost all instances on anesthetized animals.

Knocfel¹⁴ has shown evidence for widespread sympathetic excitation in man during ether anesthesia. As further evidence for sympathetic stimulation from ether and also urethane, the work of Elliott¹⁵ may be cited in which the intact adrenal glands of anesthetized cats may be depleted of its content of epinephrine. Ether also causes constriction of the spleen¹⁶. In fact, so effective is the pressor action of ether that it has been used to elevate the blood pressure during spinal anesthesia¹¹. However, ether has been shown also to have vasodilator effects¹⁷. Thus it is impossible to predict the net effect on observations pertinent to the circulation during spinal anesthesia in previously etherized animals.

Criticism of the use of morphinized animals in studies on spinal anesthesia is equally valid, since morphine promotes anoxia and hypercapnia by depressing the respiratory center. Although there is no evidence that anoxia and hypercapnia contribute to the hypotension observed during spinal anesthesia or sympathectomy, the possibility cannot be omitted that morphine also promotes muscle relaxation and may thus cause or aggravate venous stagnation. Seevers and Waters¹⁸ admit that morphine, scopolamine, barbiturates and other anesthetic agents contribute to the hypotension observed during spinal anesthesia.

In view of these facts and the lack of attempt to evaluate the effects of laboratory and surgical manipulation in the experiments supporting the principle of vasoconstrictor paralysis as the cause of hypotension in spinal anesthesia, experimental work on anesthetized and traumatized animals cannot be accepted as valid support for this thesis.

THEORY OF STAGNATION IN THE POSTARTERIOLEAR BED

If vasodilatation is the cause of the fall in blood pressure in spinal anesthesia, there should be an increased venous pressure and cardiac output, provided the reduction of blood pressure is moderate in degree. However, if venous stagnation is the cause, it should be accompanied by a decreased stroke volume and decreased cardiac output. Schubert¹⁹ reports cardiac output in 14 cases determined by Grollman's technic with anesthesia as high as the xiphoid or nipples. In 10 of these the cardiac output fell as compared with the control value before anesthesia, and the blood pressure was noted to decrease in proportion. In the other 4 cases, the cardiac output increased with increased systolic pressure in 2, no change in 1 and a slight fall in 1. He also noted clinically that the veins were collapsed and interpreted this as evidence for decreased venous pressure. The arteriovenous oxygen difference was increased. These data led the author to conclude that the fall in cardiac output resulted in a decreased arterial pressure and that decreased cardiac output was due to an impaired return to the heart. This, in turn, was attributed to paralysis of the vasoconstrictor nerves. The difficulty

of reconciling decreased venous pressure, decreased cardiac output and increased arteriovenous oxygen difference with arteriolar dilatation short of circulatory collapse is not explained. If the blood pressure changes are due to arteriolar dilatation, the reverse should be the case, that is, an increased cardiac output, increased venous pressure and decreased arteriovenous oxygen difference.

Other data supporting the notion of venous stagnation as the causative factor in the production of hypotension in man are available in the literature. Investigations of Burch and Harrison²⁰ and of Koster²¹ and investigations presented here have demonstrated a fall in cardiac output of greater or less degree during spinal anesthesia. Schubert¹⁹ has shown an increased arteriovenous oxygen difference. The effects of high spinal anesthesia on venous pressure in man have been studied²². A fall in venous pressure of 25 per cent and a parallel fall in arterial pressure in anesthesia of the fourth thoracic vertebra or above was recorded. It was also pointed out that the venous pressure will fall in high spinal anesthesia irrespective of arterial pressure changes. As a corollary to venous stagnation, the circulation time should increase. An increase has been observed in man during high spinal anesthesia²³. Finally, if arteriolar dilatation is not the important factor in the hypotension of spinal anesthesia, the diastolic blood pressure and the over-all peripheral resistance will be relatively unaffected. Smith and his associates²⁴ demonstrated remarkably little change in the diastolic blood pressure during high spinal anesthesia in man, and it has been pointed out that peripheral resistance decreased significantly in only 1 of 7 patients, decreased slightly in 2 others, was unchanged in 2 and increased in 2²⁴. Thus the preponderance of evidence controverts the thesis of arteriolar vasodilatation as the cause of hypotension during high spinal anesthesia and supports the principle of postarteriolar bed stagnation as the most important factor. In this connection, in order to evaluate the response to spinal anesthesia seen in the operating room, it is interesting to point out the effects of high spinal anesthesia on the circulation in normal man under standard conditions not given premedication or operated on and to contrast the results with those seen during surgical manipulations.

Smith and his associates²⁴ studied 18 subjects in whom anesthesia reached at least as high as the fifth thoracic with motor paralysis to the lower extremities, abdomen and thorax. In 2 of these subjects the systolic and diastolic pressures were well maintained. The remaining subjects had some decrease in either the systolic or the diastolic pressure or both. However, the systolic pressure fell more than the diastolic and in all but 5 instances the diastolic did not fall below 60 mm of mercury and frequently maintained its control level. The average fall in mean pressure was only 14 per cent in all cases. Since the heart rate was reduced only slightly, it was postulated

that the fall in arterial pressure (which was not pronounced) was due to a fall in stroke volume occasioned by a decreased venous return because of pooling of blood in the paralyzed musculature. These observations were strengthened by studies²¹ which showed that there was a reduction in cardiac output measured by the ballistocardiographic method in all of 7 instances. We observed relatively minor changes in heart rate and demonstrated that the reduction in cardiac output was due to a fall in stroke volume. We also observed an average fall in mean pressure of 14 per cent as measured by the Hamilton optical manometer after direct arterial cannulation, with anesthesia to the fifth thoracic or above.

The data cited were obtained in the presence of adequate denervation of the vasomotor fibers in the anterior spinal roots by spinal anesthesia. Information on this point was obtained by a comparison of the responses to postural change and the inhalation of low oxygen atmospheres and excess carbon dioxide in normal and anesthetized subjects. Hypercapnia in the normal subject produces an instantaneous and

decided rise in systolic and diastolic pressure. This response was absent in spinal anesthesia to the fifth thoracic vertebra or above. Anoxemia likewise produces some hypertension in normal man but does not in high spinal anesthesia. Finally the normal person responds to the upright posture with a well maintained blood pressure owing to vasoconstriction. The erect position, on the other hand, when high spinal anesthesia is given, causes a fall in blood pressure with the systolic falling faster than the diastolic, a bradycardia, vertigo and syncope. These effects are not instantaneous but occur gradually over one to three minutes. The evidence cited demonstrates the effectiveness of sympathetic denervation in high spinal anesthesia.

CLINICAL STUDIES

To illustrate the contrast in hemodynamic activity of patients in the clinic with man not operated on, 243 consecutive clinical patients on whom operation had been performed during spinal anesthesia were analyzed in an entirely unselected manner. The only criterion was the requirement that anesthesia was at the sixth thoracic vertebra or above. Various drugs commonly used in spinal anesthesia, such as procaine hydrochloride, nupercaine, pontocaine hydrochloride, intracaine and monacaine, were employed. Most patients

had previously been given small amounts of morphine and scopolamine and some had been given soluble pentobarbital also. A prophylactic injection of epinephrine sulfate was given intramuscularly to some patients before the anesthetic, and others received the drug to combat a fall in blood pressure during the course of the procedure. Various operations were performed but the majority were intra-abdominal manipulations. Criteria as to severity of blood pressure fall were arbitrarily selected. A fall in mean pressure of 40 per cent or more was considered severe, a reduction of 20 to 39 per cent moderately severe, and one of 1 to 19 per cent slight. In addition, there were patients who had no reduction or had a definite rise in blood pressure.

It is apparent from the accompanying table that 30 per cent of the patients had a severe fall in blood pressure and 21 per cent a slight fall and for 9 per cent no fall was recorded. A total of 70 per cent of patients exhibited significant hypotension. These findings contrast strongly with the effects of spinal anesthesia on the blood pressure of normal man in the supine position not given premedication or operated on. Smith and his associates²² and we²¹ found no instance of severe fall in blood pressure as defined here and a moderately severe fall in mean pressure in only 25 per cent of the cases studied as compared with 40 per cent in the operative series. In round figures, almost three fourths of the clinical patients exhibit significant hypotension whereas less than one fourth of the subjects not operated on show such changes.

Another extremely significant fact is not shown in the table. The fall in blood pressure, regardless of the type of surgery performed, occurred after the beginning of surgical manipulations in practically all instances. The manipulation may be rapid change of position, abdominal incision, turning against the patient's thorax, handling of viscera, hemorrhage or the use of abdominal packs. That surgery in its various aspects is an important factor in producing a fall in blood pressure in spinal anesthesia seems obvious. The patient whose sympathetic nervous system is extensively denervated by spinal anesthesia (sixth thoracic vertebra or above) is competent from the point of view of the circulation to handle his needs in the resting state in the supine position, but trauma of any sort concomitant with operative manipulation in the face of vasomotor paralysis and loss of vasomotor defense may precipitate a significant reduction in blood pressure and, if severe enough, complete circulatory collapse.

It is interesting to note the effect of major disturbances of the circulation and respiration preoperatively on the course of blood pressure changes when surgery is being done during spinal anesthesia. Preoperative pulmonary complications have no noticeable influence on the maintenance of blood pressure during spinal anesthesia. The effect of arterio-sclerotic cardiovascular disease is uncertain, since it was present preoperatively in 13 per cent of cases showing no fall in blood pressure and had the same incidence in the group exhibiting severe falls in blood pressure as in any other group.

It is noteworthy that the incidence of nausea as a complication during high spinal anesthesia is unaffected by the extent of the fall of blood pressure, whereas the incidence of emesis decreases with decreasing falls in blood pressure. Another interesting fact is the occurrence of syncope in 6 per cent of the cases

showing severe falls in blood pressure, 1 per cent in the moderately severe group and in no cases in which blood pressure fell only slightly or not at all. The postoperative complications as listed are self explanatory. Emphasis should be placed on the absence of postoperative shock in the groups showing little or no change in blood pressure and the absence of mortality in the group exhibiting no fall in blood pressure.

The problem of treatment of the hypotension observed during spinal anesthesia is important. Treatment should be directed toward increasing venous return to the heart to maintain adequate cardiac output and increasing the oxygen tension of partially unsaturated arterial and venous blood. The administration of oxygen provides a means for satisfying the latter need. Clinically and experimentally, oxygen administration is of definite benefit in combating hypotension and the nausea and vomiting which may occur with spinal anesthesia.

Hypotensive episodes during spinal anesthesia have been treated clinically with various pressor drugs such as ephedrine, paredrinol and neosynephrin hydrochloride. The mechanism of the beneficial effects produced by these substances is often difficult to evaluate. Paredrinol²⁵ and neosynephrin hydrochloride²⁶ initiate an elevation of blood pressure as a result of increased peripheral resistance. Ephedrine apparently produces a pressor effect by increasing venous return, right auricular venous pressure and cardiac output. This pressor response to ephedrine may occur in spite of decreased or unchanged peripheral vascular resistance.²⁷ Therefore, on the basis of the facts outlined ephedrine is the drug of choice to counteract the hypotension of spinal anesthesia. The clinical findings support this concept, since alleviation of the symptoms of circulatory depression is readily accomplished with ephedrine.

The problem of prophylaxis for the hypotension of high spinal anesthesia is of no less importance than treatment. A severe fall in blood pressure cannot be considered physiologic, and its occurrence and duration during anesthesia adversely affect the morbidity and mortality of the surgical procedure being completed. The selection of patients is the primary consideration. Those with circulatory disturbances will respond poorly to further embarrassment of this function. The use of oxygen to prevent hypoxia and of pressor drugs, particularly ephedrine, to maintain blood pressure within normal limits is as definitely prophylactic as therapeutic. The other factor in prophylaxis is the role of the surgeon. This has escaped emphasis in discussions on the subject. Indubitable evidence that in man who has not been operated on the fall in blood pressure does not parallel that observed during surgery points to surgical manipulations as a factor of primary consideration. The patient with high spinal anesthesia and the major portion of his vasomotor defensive mechanisms paralyzed should have the need for such response minimized. Unnecessary surgical trauma is never justified. During high spinal anesthesia it should be eliminated and in addition the unavoidable manipulations carried out with extreme care. High spinal anesthesia is not the procedure of choice for an operation which must be completed with severe loss of blood, abdominal positional changes or

excessive trauma. The surgeon whose technics include rough handling of tissues, their wide exposure and other traumatic factors will not find his results improved with high spinal anesthesia despite the more uniformly convenient operating conditions.

ABSTRACT OF DISCUSSION

DR SIDNEY C WIGGIN, Boston. I agree with Dr Papper that we have been able to control circulatory changes for the most part by the use of vasoconstrictor drugs, together with the use of many other agencies, such as preparation of the patient, recognition of variations in technic and action of different agents, chiefly maintenance of oxygenation and minute by minute observation of the effects of the drugs and surgery with the early treatment of complications. Spinal anesthesia can be the safest and most efficient method for operations below the diaphragm in selected cases. In the relief of pain in the present worldwide conflict it will be used more than any other method, especially when it has been estimated that over 50 per cent of wounds occur below the hips. To explain satisfactorily the physiology of spinal anesthesia, we must consider the theories mentioned by Dr Papper. Although perhaps conflicting and not complete in themselves, each theory contributes to our knowledge of the effects of spinal anesthesia on the vital centers, and structures of the body which control the physiologic functions. Thus, SeEVERS and WATERS in 1931 described the local diffusion of procaine hydrochloride in the subarachnoid space resulting in paralysis of the accessory muscles of respiration, and they recommended oxygen for the ensuing anoxia. NOWAK in 1932 demonstrated central absorption of procaine from the spinal canal by dyes introduced into the spinal fluid and isolated in the urine. He then introduced lethal doses of procaine into the veins of a series of cats and intraspinally below the second lumbar vertebra into another series and showed a similar development of toxic symptoms and death in both groups, with the detection of procaine in the urines. I agree with Dr Papper that the most serious complications in spinal anesthesia are principally the result of the lack of individualizing the patient and the recognition of the factors related to surgery itself. ROVENSTINE's description of traction reflexes has clearly shown the part overstimulation of vital nerve centers plays in the disturbance of the patient's physiologic balance in spinal anesthesia and surgery.

DR STUART C CULLEN, Iowa City. The lack of conformity of opinion in explaining the hypotension associated with spinal anesthesia and the diametrically opposed interpretations of data obtained in studies of this subject seem to indicate an incomplete understanding of some fundamental factor. That the fundamental derangement in circulatory stability is a consequence of the absence of sympathetic control is a theory fairly well accepted. The nature of the sites of action of this control, their extent and the degree of autonomous integrity of the peripheral vascular system in the absence of sympathetic control are the real problems to be answered. Dr Papper's theory of maintained arteriolar competence with venocapillary stagnation is logically considered. It is difficult, however, to reconcile this arteriolar competence with incompetent postarteriolar capillaries. Must one assume that sympathetic impulses are nonessential to the maintenance of tone of the arteriole and essential to the maintenance of tone in the postarteriolar capillaries? The evidence presented does not exclude relative degrees of arteriolar incompetence. By the criteria employed such as reduced venous pressure, decreased cardiac output and increased difference in arteriovenous oxygen saturation, to establish arteriolar competence, relative degrees of arteriolar atonicity are not revealed. The moderate degrees of lowering of diastolic pressure can be interpreted to indicate some decrease in peripheral resistance due to loss of arteriolar tone. Dr Papper has emphasized the significance of mechanical interference with the dynamics of a peripheral vascular system under the influence of spinal anesthesia. This is a contribution of much practical importance. It does not seem logical to assume that "vasomotor defense" is lodged entirely in the postarteriolar bed in view of anatomic evidence that arterioles are

²⁵ Ranges H A and Bradley S E. Personal communications to the authors.

²⁶ Keys Ancel and Violante Antonio. The Cardiovascular Effects in Man of Neosynephrin. *J Clin Investigation* 21: 112 (Jan) 1942.

richly supplied with sympathetic nerve fibers. It does seem logical, however, to assume that in the maintenance of normal tension by integration of the peripheral vascular system through the sympathetic system the arteriole, as well as the capillary bed, plays a significant role. In the absence of sympathetic integration, autonomous arteriolar control is sufficient to maintain relatively normal tension in the resting supine state, but not sufficient to effect the proper distribution of blood in other positions and in response to unusual demands.

DR HENRY K BEECHER, Boston. The views that Dr Papper has presented have a considerable basis in the papers that Smith, Rovenstine, Chasis, Goldring and that group recently presented. Those papers and Dr Papper's presentation suggest that a question might be raised here as to how far conclusions can go when based on studies of a single organ or system. I believe we all agree that it is not wise to draw many general conclusions about the circulatory effects of spinal anesthesia from observations of the circulation of the skin. We all appreciate the fallacies inherent in that and I want to call attention to a similar question in regard to the paper presented today, and the earlier papers, namely, the hazards of drawing too many conclusions from the kidney. It is well to speak of this in the light of recent observations by Dr R H Smithwick, who has found that the kidney is to some extent innervated through pathways that come from well above the level that is reached by the high spinal anesthesia of the study under discussion. The kidney innervation is certainly widespread and extensive, it may rise as high as the second or third dorsal region. Furthermore, acute denervation as accomplished with local anesthetics may not give an accurate picture of persistent denervation effects. Such studies as these should include the behavior of the kidney under various reflex stresses and strains as Smithwick has pointed out.

DR E M PAPPER, New York. In answer to Dr Cullen I would state that the thesis maintained is that arteriolar dilatation is not an important factor in normal man, not operated on, under the standard conditions of our investigation, and that all the evidence indicates that whatever hypotension occurs is due to a fall in cardiac output, which, in turn, is attributed to failure of circulation in the postarteriolar bed. Concerning the question Dr Cullen raised about the individual's vasomotor defense during surgery, I agree that other factors might play an important part in the hypotension during clinical surgery. In fact, that is one of the strong points of our thesis in this argument, that the patient who is operated on is a different individual from the one who is not. Since he is adequately denervated as far as the sympathetic nervous system is concerned, he cannot compensate for the changes that occur during manipulation, trauma, hemorrhage and change of position. Whether that is due to superimposed arteriolar dilatation during surgery or whether it is due to failure of arteriolar constriction beyond normal tone, I don't think we can say at the present state of our knowledge. In answer to Dr Beecher's question, the systemic circulation has been studied with direct arterial cannulation for arterial pressure and by the ballistocardiac method for cardiac output. We are able by these methods to measure the actual cardiac output and the actual mean pressure and thus to determine the overall peripheral resistance which must lie largely in the arterioles. Therefore, the work does not rest entirely on renal blood flow but on direct observations in the general circulation.

Tuberculosis in Old Age—It is erroneous to assume that tuberculosis occupies a subordinate position in old age. Compared with the number in the younger age groups fewer senile persons fall sick or die from the disease, but there is no percentage decrease of tuberculosis in the aged. The mortality rate of the infection for all white persons (1 to 74 years) insured by a large company for the years 1931 to 1935 was 68.4 for males and 98.6 for females. Between the ages of 20 and 24 the rate was 54.8 for men and 84.8 for women. In the group 64-74 years there was a striking rise and a reversal of sex differences, 130.5 for males and 66.7 for females—Mueller-Deham, Albert, and Rabson, *S. Milton. Internal Medicine in Old Age*, Baltimore, Williams & Wilkins Company, 1942.

SPINAL ANESTHESIA

FACTORS INFLUENCING ITS SUCCESS

LEO V HAND, M.D.

BOSTON

The success of any anesthesia is dependent on three general factors: (1) the patient and his disease,¹ (2) the choice of agent and method of administration² and (3) the skill and experience of the person administering the anesthesia. This is especially true when anesthesia by means of the subarachnoid route is elected.

My purpose in this paper is to mention or review some of the objective findings, observations, points in technique and corrective steps instituted that have an important influence on the success of anesthesia by the subarachnoid route. For purposes of coherence, these specific clinical factors will be presented under the following subtitles: (1) preparations of the patient including preoperative medication,³ (2) choice of agent and method, and (3) administration of the agent and its supervision.

PREPARATION OF THE PATIENT

The preparation of a patient for spinal anesthesia not only necessitates a thorough knowledge of the objective findings which may influence its course but also includes an intimate knowledge of the patient's emotional status toward or past experience with this or allied methods of anesthesia. Patients in shock⁴ are known to be poor candidates for spinal anesthesia. Recent experiences⁵ among war casualties have further strengthened this observation. Patients with moderate to severe anemia tolerate the usual doses of agent poorly. Patients with anemias, cachexias or other blood dyscrasias should receive blood transfusions prior to the day of operation. Also it is inadvisable to elect spinal anesthesia in the presence of neuropathologic findings within the cerebrospinal system. Occasionally spinal pain following anesthesia has been attributed to the anesthesia when subsequent examination has revealed evidence of a concomitant neuropathologic condition.

A preoperative interview acquaints the patient with the anesthetist and the contemplated method. It also elicits valuable information from the patient as to his reactions to an anesthesia or his past experience with a similar anesthesia. Many patients are not receptive to spinal anesthesia for one of the following reasons: 1 The patient prefers to be asleep. 2 From hearsay, usually grossly exaggerated, the patient has been warned against spinal anesthesia. 3 The patient's local physician warns him against spinal anesthesia. 4 The patient has had a previous, decidedly unpleasant experience with an inadequate spinal anesthesia. 5 The patient tells the anesthetist of untoward reactions when this method was employed on a former occasion. Of these five reasons, the one requiring the most attention and investigation is the last—that is, the ques-

tion of idiosyncrasy. The most difficult to counteract is the fourth—a "gun shy" patient. The most annoying is the careless, thoughtless or officious remarks of an inexperienced physician. The easiest to cope with is the first—the desire to be asleep.

As a result of this preoperative visit and review of objective findings, the anesthetist is better able to evaluate the anesthetic risk of the patient. Depending on this information and grade of risk, the dose of preoperative medication is determined. The doses of preoperative medication usually ordered for good risk adult patients are pantopon $\frac{1}{8}$ grain (0.02 Gm), scopolamine hydrobromide $\frac{1}{150}$ grain (0.4 mg) subcutaneously two hours before the scheduled time of operation and soluble pentobarbital 3 grains (0.2 Gm) by mouth one hour before the operation. The soluble pentobarbital is given by rectum when oral medication is contraindicated. Patients with this medication usually arrive in the operating suite in a drowsy or euphoric state of mind, ideal for surgery on a conscious patient. Occasionally patients show little effect from this medication, in such instances medication is reinforced just before spinal puncture with varied doses of morphine $\frac{1}{12}$ to $\frac{1}{6}$ grain (0.005 Gm to 0.011 Gm) and scopolamine hydrobromide $\frac{1}{100}$ to $\frac{1}{200}$ grain (0.2 to 0.3 mg) intravenously.

CHOICE OF AGENT AND METHOD

The agent and method to be employed in spinal anesthesia depend on the contemplated operation. The more commonly employed agents are procaine hydrochloride, pontocaine hydrochloride and nupercaine. The respective indications for these three agents as employed at the Lahey Clinic have been reported in detail elsewhere.⁶ Pontocaine hydrochloride combined with dextrose, as originally reported by Sise,⁷ is most commonly used. By the use of the Sise technique (gravity method), the maximal concentration of the drug in the subarachnoid space is deposited at or around the nerve roots supplying the site of operation. This results in maximal concentration of anesthetic in these areas. This heavy solution with the patient in a supine position tends to result in a high sensory or posterior root anesthesia and an appreciably lower, and thus safer, motor or anterior root anesthesia.

Recent developments in the method of administration or technic have eliminated the former objection of limited or too short duration of anesthesia. Present day methods may be divided into the conventional or single dose method⁸ and the continuous or fractional method⁹ with repeated doses of an agent as needed. It is the opinion of the members of this department that fractional spinal anesthesia¹⁰ will not completely supplant the conventional method of administration. In our opinion, indications for the fractional method are (1) operations in which the anticipated duration will exceed the duration usually obtained by the single dose method and (2) operations of unpredictable duration.

ADMINISTRATION OF AGENT AND ITS SUPERVISION

To some anesthetists the review of minor points of the technic of lumbar puncture may hold some interest. To a few it may be instructive. The administration and supervision of an agent is essentially technical and is governed by three components (a) the equipment, (b) the agent and (c) the administrator.

The syringe and its size are dependent on the agent elected and the quantity deemed sufficient for anesthesia. The type and gage of needle have an influence on the success of spinal anesthesia. Clinical investigations¹¹ by the late Dr Sise suggest that the gage of the needle has a definite influence on the incidence of postlumbar puncture headache. For patients with a planned, very short bed stay, that is six to twenty-four hours, we employ a No 24 gage needle. For routine conventional spinal anesthesia we use a No 21 gage needle. This 21 gage needle has a flexible, seamed, gold shaft and nickeloid hilt. Since its introduction we have not had a needle break within the body tissues during lumbar puncture. For fractional or continuous

Moore introducer

spinal anesthesia we use a special No 19 gage lumber nickeloid needle.

An introducer is employed to guide this flexible, soft needle through the interspinous ligament. The new introducer illustrated, devised by Dr George C Moore¹² on the principle of a groove director, has been an invaluable aid in facilitating accurate, speedy lumbar puncture when the flexible continuous spinal needles are used. This introducer can readily be removed without disturbing the indwelling needle. The combination of indwelling introducer and needle should be avoided. To my knowledge the only needle used for continuous spinal anesthesia broken within a patient's back was when a rigid walled introducer acted as a shearing blade when the patient was turned from a lateral flexed to a supine extended position.

When the pontocaine-dextrose technic is employed, the patient's head is always flexed so that the most dependent area of the spinal column is approximately between the second and the fourth thoracic segment. This tends to prevent upward cervical and medullary

11 Sise L F and Swinton N W A Method for the Prevention of Postpuncture Headache in Cases of Low Spinal Anesthesia S Clin North America 19 695-698 (June) 1939
12 Moore G C Personal communication to the author

progression of anesthesia. With this technic the upward progression of anesthesia is obtained by gravity. The patient is placed in a 10 degree Trendelenburg position for a very short period (one to two minutes). The degree of the Trendelenburg position is to be judged not by the degree of table slant but rather by the actual slant of the spinal column. An obese person with narrow shoulders and broad buttocks will actually be in a 15 degree Trendelenburg position when a table tilt is recorded at 10 degrees. It is in such instances that the complication of severe respiratory embarrassment occurs most frequently.

The usual site of election for lumbar puncture is the third lumbar interspace. In operations in which the contemplated procedure will be entirely in the upper part of the abdomen, a better concentration of anesthesia¹³ is obtained and maintained when lumbar puncture is made in the second lumbar interspace. The spinal needle should not be introduced with any degree of roughness. When so employed the usual result is not only a painful lumbar puncture but also traumatization of periosteum. Lumbar puncture in some obese persons may be a difficult procedure. In such instances the introducer or needle may be used to locate the interspace. If puncture is not obtained after one or two attempts, the employment of geometric principles will always facilitate midline puncture. This is easily accomplished by introducing the needle toward the left side until radiating pain is elicited in the left knee, then repeating the procedure toward the right side until similar radiation of pain results in the right knee. Having thus determined lateral nerve emergence one bisects this angle and a painless successful puncture is obtained. These steps save unnecessary, haphazard repeated attempts, usually accompanied by considerable periosteal traumatization and pain. Again, in patients requiring lumbar puncture twenty-four to forty-eight hours after encephalography or spinography, the decided diminution of spinal fluid usually results in a dura readily displaced and difficult to puncture. In such instances the following steps facilitate puncture: (a) a drop of fluid in the hub of the needle will be sucked in when the epidural space is entered—thus an important landmark of the proximity of the dura and (b) a needle with a bevel angle of less than 90 degrees and a sharp cutting point facilitates this dural penetration.

With the special needle for continuous spinal anesthesia it is advisable to persist in lumbar puncture manipulation until fluid can be aspirated readily with the patient in the supine position, even if this necessitates a repuncture. In instances in which this precaution was ignored, invariably attempts to maintain high anesthesia by subsequent injections were either difficult or unsuccessful.

The accurate determination of heights of anesthesia is an important step. It informs the anesthetist of approaching, unnecessary and potentially dangerous heights of anesthesia. It determines the adequacy of the height of anesthesia. An inadequate anesthesia without a supplemental remedy results in a disturbed patient as well as exceedingly poor operating conditions. When testing, the more accurate response is obtained by negative suggestion. For instance, it is preferable to say "You do not feel" rather than to ask "Do you feel?" The patient's response to the usual type of questioning will depend on his tolerance to pain and his

emotional status. When the suggestive negative form is employed, the patient will quickly and emphatically correct you in the presence of definite pain stimuli. In patients with language difficulties or excessive medication, objective responses, particularly facial wincing to test stimuli, are good indexes of the upward progression of anesthesia.

After satisfactory anesthesia has been obtained, the clinical course is checked frequently and recorded at at least five minute intervals. From the information obtained, the anesthetist is better able to safeguard against or institute early corrective measures to combat operative complications. These observations consist in blood pressure, pulse and respiratory recordings, determination of the presence or absence of intercostal breathing and a close watch for early signs of beginning loss of anesthesia.

In all operations of a serious nature or when there is a question of long duration an intravenous infusion is started and maintained throughout the operation. This infusion affords a ready access for corrective measures, such as blood and intravenous medication, to combat certain operative complications and is a channel by which complementary intravenous agents may be employed.

COMMENT

In many operations in the upper part of the abdomen, a complementary agent,¹⁴ either inhalation or intravenous in nature is employed for the following reasons. The first and most important is to lessen objective response to traction stimuli, thus lessening the severity of certain potential operative complications. The second is that many patients prefer to be asleep. The third is that it permits greater freedom of discussion of the pathologic conditions and contemplated treatment.

The immediate post-operative orders for sedation and fluid are usually the responsibility of the anesthetist. He is better qualified to judge and is familiar with the physiologic state of the patient resulting both from anesthesia and from the operation.

The operative complications associated with and most likely caused by traction reflexes are appreciable falls in blood pressure with little to no pulse disturbances, usually accompanied by nausea and retching in a conscious patient. This circulatory depression is not as severe and the gastrointestinal response is eliminated with the patient asleep. In instances of nausea and retching oxygen is routinely administered. When the blood pressure recordings approach 50 per cent of the original preanesthetic systolic levels, a vasodepressor drug is given to inhibit further falls in blood pressure and to treat the present depressed state. The pressor drug combination usually employed is an intramuscular injection of pitressin¹⁴ 5 units and ephedrine $\frac{3}{8}$ gram (0.024 Gm.). With this combination not only is blood pressure improved but this improvement is sustained for an appreciable period in the nature of a plateau effect.

Transfusions of whole blood plus oxygen and pressor drugs are given in instances of shock or impending shock. No substitute such as plasma or albumin is as effective as whole blood, particularly in instances of shock due to loss of blood.

Second in frequency to circulatory depression is loss of anesthesia. With the continuous spinal method this complication is eliminated. The single dose administra-

¹³ Hand L. V. and Sise L. F. Anesthesia for Gastric Surgery, S. Clin. North America 21: 803-815 (June) 1941.

¹⁴ Raginsky B. B. The Present Status of Anesthetics in Anesthesia, Tr. Am. Coll. Surgeons 1: 66-73 (July) 1938.

tion necessitates a supplementary anesthesia of sufficient depth to obtain motor relaxation. The following signs are indicative of beginning loss of anesthesia. The earliest is a vasomotor change manifested by perspiration. Next the patient complains of vague discomfort. Simultaneous with this discomfort, the abdominal viscera tend to balloon up and fill the incisional opening. The last is beginning loss of relaxation. Through inexperience or careless supervision signs of loss of anesthesia are not recognized until beginning loss of relaxation. In such instances the transition to an inhalation anesthetic results in a very stormy and disturbing period for the patient.

Occasionally spinal anesthesia may become too high, with resultant progressive respiratory signs of ascending anesthesia. These progressive signs are absent intercostal to reversed intercostal action accompanied by suprasternal notch tugging and a progressive increase in accessory respiratory muscle action to absence of respiration. The treatment of this complication will depend on the degree of respiratory involvement. The mental state of the patient plus the objective degree of paralysis usually influence further procedure. Usually light supplementary anesthesia will suffice to alleviate the disturbed mental state of the patient. If the patient is kept abundantly supplied with oxygen it is remarkable how little disturbance is caused him even by a considerable degree of intercostal paralysis. In instances of complete respiratory paralysis it is necessary to resort to passive breathing and to insure a patent and clear airway. A patent airway is best obtained by means of intratracheal intubation. The duration of intercostal paralysis is dependent entirely on the duration of anesthesia.

No method of anesthesia can excel spinal anesthesia in regard to the relaxation obtained especially in abdominal surgery. Certain physiologic pharmacologic and technical precautions or specific factors influence its success.

605 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR R J WHITACRE, East Cleveland, Ohio. Dr Hand's presentation should do much to stimulate our interest in obtaining a better understanding of certain factors essential to the safe and satisfactory use of spinal anesthesia. The relatively high morbidity and mortality rates of spinal anesthesia are inconsistent with the impression that spinal anesthesia is a simple mechanical process of injecting drugs into the subarachnoid space. It requires as much experience, knowledge and skill as any other type of anesthesia. The progress in spinal anesthesia has been so rapid that the number of complications can be materially reduced if the available information is properly utilized. Dr Hand has called attention to the advisability of using less than the ordinary dose of the anesthetic agent for the impaired risk patient. Although this factor is generally recognized in inhalation anesthesia, it is frequently ignored in estimating the dose of the spinal anesthetic. Certain other cases such as full term pregnancy also require less than the ordinary dose. The concentration of the anesthetic solution when injected into the spinal canal must be rigidly controlled. With agents of different potencies it is necessary to vary not only the dose but also the concentration of the drug. I should like to emphasize the need of preventing hypoxia during spinal anesthesia. Dr Hand has stressed the means of maintaining circulation so that an adequate supply of oxygen may be transmitted from the lungs to the tissues. Simultaneous circulatory and respiratory depression occurs so frequently during spinal anesthesia that one cannot assume that every patient is ade-

quately oxygenated when breathing air. To many patients it is of advantage to administer oxygen with a gas machine. This provides a positive means of not only increasing the tension of oxygen but also evaluating the patient's actual respiratory exchange at all times. This is a more reliable index of pulmonary efficiency than the presence or absence of intercostal activity. The three factors adequate oxygen in the inspired atmosphere, adequate pulmonary ventilation and adequate circulation require particular attention during spinal anesthesia. When intentionally supplementing spinal anesthesia, it is frequently possible in selected cases to use less than the usual dose of the agent. This is another important means of increasing the safety of spinal anesthesia. In reference to continuous spinal anesthesia it is reasonable to say that the time or length of operation is not the only indication. It is equally important to use continuous spinal anesthesia for certain poor risk patients regardless of the duration of the operation.

DR VIRGINIA APGAR, New York. Dr Hand has summarized well the main problems concerned with the proper management of a patient under spinal anesthesia. There are three points on which I wish to comment. 1. The method he describes to locate the spinal canal in difficult situations depends on the production of paresthesia. I think any regional method which relies on paresthesia as a definite landmark is to be discouraged. It is bad enough to produce it accidentally. May I suggest in such cases that entrance to the spinal canal by way of the paravertebral route, passing the needle cephalad to the transverse process, is frequently easier than by the midline approach and is usually not accompanied by pain. 2. One reliable method for determining the descending level of spinal anesthesia has been implied by Dr Hand but not mentioned specifically. As with all techniques a careful observation and interpretation of respiration is indispensable. The encroachment of the intestine on the operative field after it has supposedly been well packed off is due to the increased tidal volume of the patient as well as to the loss of the hypertonic state. In my experience an increase in respiratory exchange usually precedes vasomotor changes or complaints by the patients or surgeon. 3. No one can predict accurately the future place of the continuous spinal method. I have a feeling that its use will be more widespread than suggested by Dr Hand. In general I believe that it will be used in cases of spinal anesthesia in which 100 mg of procaine hydrochloride is not considered sufficient. We are permitted to use the least toxic regional drug—at present procaine—in all cases, and in much more accurate and individualized doses. The complete absence of the most serious spinal complication, respiratory paralysis, outweighs the occasional hypotensive state which is difficult to control.

DR F ELMORE HUBBARD, Montclair, N J. I want to ask Dr Hand the name of the groove introducer and where one can procure it.

DR GEORGE C MOORE, Boston. Regarding the grooved introducer, I want to say that it has been found to be just as satisfactory to use it with a small needle, 21 or 22 gage, as with the needle for continuous spinal anesthesia. With the smaller needle, of course, it may or may not be removed. I am not sure I am entitled to priority in originating it because I learned this morning that Dr Batten of the Methodist Hospital of Brooklyn has devised a somewhat similar instrument. I haven't seen his, so I can't describe it. If I may answer Dr Hubbard the McGregor Instrument Company of Needham Mass., is making the instrument.

DR LEO V HAND, Boston. In regard to Dr Appgar's suggestions, I agree with her relative to the method of paresthesias in developing anesthesia. That is not advisable, but frequently of necessity we employ it. For a particularly obese individual and when I do not care to have him sit up or follow the usual procedure it frequently proves in my hands to be a quicker method of locating the spinal canal. As to the future of continuous spinal anesthesia, that is a question. In the hands of surgeons a continuous spinal anesthetic may supplant the conventional dose method. I fear the situation may arise when all they have to do is turn to the nurse or intern or whoever is supervising and say "More relaxation" irrespective of the physiologic state of the patient.

MICROAEROPHILIC HEMOLYTIC STREPTOCOCCUS INFECTION CAUSING DESTRUCTION OF NOSE

MAURICE J COSTELLO, M D

NEW YORK

Prior to 1924, hemolytic streptococcus gangrene was reported under various clinical titles which included contributions by Seeman,¹ by Hawkins² and by Stirling³ under the title of "gangrene of the scrotum and penis" and as "streptococcus scrotal and penile gangrene" by Campbell.⁴ In 1924 Frank L. Meleney⁵ reported 20 cases of hemolytic streptococcus gangrene from the clinic of the Peking Union Medical College in China, where he stated that the disease was fairly common. Fedden⁶ in 1909 and Pfanner⁷ in 1918 described cases of acute infective streptococcus gangrene of the extremities which Meleney thought were similar to those he studied in the Orient.

Since 1924 reports have appeared on the clinical recognition, on the bacteriologic studies, and on the treatment of an infection from which it is to be differentiated, namely that caused by the microaerophilic hemolytic streptococcus. The majority of these articles are the lucid contributions of Meleney and his co-workers. Unfortunately microaerophilic hemolytic streptococcus infection of the skin is seldom diagnosed early because of ignorance of its existence—the disease is admittedly rare—and also because of failure to order anaerobic as well as aerobic cultures of all infections of the skin of an obscure nature.

The request for anaerobic culture studies is so infrequent that many bacteriologic laboratories are not equipped to perform them properly.⁸ The causative organism of this infection has been called microaerophilic because it grows best under slightly reduced oxygen tension.⁹ It is for this reason that specimens for bacteriologic study should be taken from the sinuses and the undermined edges of the wound.

From a study of the literature it appears that any portion of the skin may be affected by this disease, but it occurs most frequently on the extremities, especially in men. The perineum, scrotum and penis are often affected. This is probably due to the proximity of these organs to the anal orifice, the hemolytic streptococcus being often found in the intestinal tract.¹⁰

Meleney's clinical description of this disease, repeated in all his writings, should make it as recognizable as erysipelas, from which it is to be differentiated. His further studies on the bacteriology of the causative organism—the microaerophilic hemolytic streptococcus—should make confirmation of the diagnosis a relatively simple matter, if this infection is kept in mind. Effective treatment then can be instituted promptly, preventing suffering, loss of time, money and life itself.

The organisms causing this infection may enter the body following superficial injury to the skin, a scratch, an abrasion, a boil, a herpetic lesion, a hypodermic injection, a severe injury or a minor or major surgical procedure.¹¹

Prolonged suppuration leads to the development of ulcers having undermined borders and sinuses which burrow into the deep tissues. Muscle and bone are not often affected unless injured at the time of the original trauma. Severe hidradenitis suppurativa of long standing involving the axillas and inguinal regions may be complicated by this type of infection. Several of the cases reported suggest this possibility.¹⁰

This disease may be mistaken for erysipelas, cellulitis, pyoderma gangrenosum, tertiary syphilis, tuberculosis and varicose ulcers when it occurs on the extremities. When the lesions occur on the face and especially around the nose, almost invariably a diagnosis of syphilis, tuberculosis, carcinoma or rhinoscleroma is entertained. It is during this period of mistaken diagnosis that valuable time is lost and mutilating destruction occurs.

The case I am about to report exemplifies the difficulty in diagnosing this serious infection.

REPORT OF CASE

M. J., a woman aged 59 when first seen by me on Dec 20, 1937, had an ulcer on the right side of the nasal septum and the floor of the right nasal cavity for thirteen months which had increased in extent in spite of many types of local and general therapy. The extensive ulceration involved the mucous membrane of both nasal cavities with an irregular vertical perforation of the anterior portion of the nasal septum. The floor of the ulcer was covered with tenacious seropurulent exudate. The skin of the bulbous portion of the nose was dull red edematous and tender on pressure. There was no pain but numbness was a prominent feature. The redness faded gradually into the normal skin. During the first weeks of observation by me the patient had a moderately elevated temperature 101-102 F, had frequent sweats while sleeping and complained of fatigue and shortness of breath. Frequent microscopic examinations of smears did not show Vincent's organisms or tubercle bacilli. The Gram stain showed occasional gram positive cocci which resembled pneumococci. Cultures showed hemolytic streptococci. The Wassermann reaction of the blood and the Kline precipitation test were negative on three different occasions. The sugar content of the blood was 114 mg per hundred cubic centimeters. Urinalyses showed no abnormality, and the leukocyte count was between 12,000 and 16,000 on a number of occasions. Roentgenograms of the maxillary bones showed no abnormality. A roentgenographic study of the chest revealed numerous calcifications and a general peribronchial thickening throughout each lung particularly in the inferior lobe of the right lung. Several biopsies were performed. The first showed "chronic suppurative inflammation. A specimen of the nasal mucous membrane showed a hyperkeratotic papilloma," and a specimen from the skin showed "hyperplastic inflammatory tissue."

During the first six weeks the patient received five intravenous injections of neocarsphenamine each 0.45 Gm, two of bismarsol and daily oral administration of 4 fluidrachms (15 cc) of saturated solution of potassium iodide. There was no improvement in the lesion during this treatment. Local therapy consisted of irrigations with solution of boric acid and 1 per cent aqueous solution of brilliant green and 1 per cent aqueous solution of methylrosaniline.

The patient was tested with old tuberculin by graded intradermal injections on the forearms in dilutions of 1:100,000, 1:1,000,000 and 1:10,000,000. The areas of the skin injected became erythematous and swollen, and in forty-eight hours

bullae developed at the site of each injection. These bullae were followed by ulcerations, which were of equal size despite the difference in dilution of tuberculin.

I presented the patient at the Manhattan Dermatologic Society in February 1938 with the diagnosis of pyogenic ulceration of the nose.¹²

She was again presented before the same society in April 1939 because of an exacerbation of the infection.¹³ The infection had been dormant from June 1938 to January 1939. The period of remission was ascribed to the therapeutic effect of the iodides or tuberculin.

At that time she had an extension of the ulceration of both nasal cavities with complete destruction of the lower half of the septum. The skin of the bulbous portion of the nose was dusky red, swollen and tender, and the involved area was not sharply margined. An infectious eczematoid dermatitis appeared on the upper lip. During the following five months the infectious process destroyed the columella. The patient was again given large doses of the saturated solution of potassium iodide, this time without benefit. She received adequate doses of sulfamidamide, isosulfamide and sulfapyridine without favorable effect on the infection. Prior to the onset of the disease the patient's general health had always been good except for an eruption on the palmar surfaces of the tips of the fingers during the winters of 1903, 1906, 1912 and 1913, which consisted of deep indolent ulcerations, probably papulonecrotic tuberculi. The resulting scars are still visible.

After the diagnosis of microaerophilic hemolytic streptococcus infection was confirmed by the bacteriologic studies performed by Dr Frank L. Meloney, the application of zinc peroxide cream caused gradual arrest of the infection. When the patient was last seen the disease process appeared to be controlled.

COMMENT

Treatment should be instituted immediately after the clinical diagnosis of microaerophilic hemolytic streptococcus infection is confirmed by proper anaerobic bacteriologic studies. If the infection involves a small area it should, if possible, be excised and the operative wound should then be treated with zinc peroxide paste. Skin grafting should be performed if necessary after the infection has been eradicated. Meloney advises surgical incision to encourage adequate drainage and relief of tension of the swollen tissues especially if the infection involves the extremities. Forty per cent zinc peroxide cream is made by mixing equal amounts of the potent sterilized powder and distilled water.¹⁴ Since the microaerophilic hemolytic streptococcus is an anaerobic organism living in the recesses of the burrowing ulcers and the undermined edges of the wound, zinc peroxide cream must be applied thoroughly to these areas. Every part of the infected surface must be in continuous contact with the medicament. Since not all lots of the powder are effective, they must be tested for potency,¹⁵ as the powder is therapeutically efficient only by virtue of its ability to produce oxygen when it is in contact with water. When the infected area is treated with the paste, it should be covered with wet gauze to insure constant liberation of oxygen. The gauze in turn should be widely covered with zinc peroxide ointment. The cream should never be permitted to become dry.

The sulfonamide drugs have been somewhat effective in combating this infection if administered early, before fibrosis prevents the necessary contact with the organ-

isms.¹⁶ Too much reliance must not be placed on them if after a short trial the advancing disease warrants intelligent surgical intervention.

SUMMARY AND CONCLUSIONS

1 A case of microaerophilic hemolytic streptococcus infection causing destruction of the nose was observed.

2 Infections of this type may persist for an indefinite period before their true causation is determined because of remissions which are erroneously attributed to various forms of therapy.

3 Anaerobic as well as aerobic bacteriologic studies should be made as a means of arriving at a correct diagnosis early in the course of the disease.

4 Treatment by excision, incision and zinc peroxide cream is the best means of managing this serious infection.

140 East Fifty-Fourth Street

ABSTRACT OF DISCUSSION

DR FRANK L. MELONEY, New York. I did not realize until Dr Costello's paper was received a few days ago that he had confused the hemolytic streptococcus gangrene, which I saw frequently in China and described in 1924 in the *Archives of Surgery*, with the undermining, burrowing, chronic ulcer due to the microaerophilic hemolytic streptococcus, which I have described more recently. This gives me the opportunity to point out the fundamental differences in the two, which should be clearly differentiated. This case falls into the microaerophilic hemolytic streptococcus undermining ulcer group. The hemolytic streptococcus gangrene is an acute, fulminating, rapidly extending infection of the subcutaneous tissues. The pathognomonic sign of this disease is a purplish area in the center of an extensive erythema. This appears on the fourth or fifth day and goes on rapidly to gangrene. The infection spreads in the subcutaneous tissues, producing an extensive slough of the subcutaneous fat, but it does not spread down into the deeper tissues. This is due to an aerobic hemolytic streptococcus. Probably there is an element of hypersensitivity in this infection, which may be the explanation for its appearing more frequently in China than in this country. In the last eighteen years I have seen fewer than fifteen of these infections. The chronic, undermining, burrowing ulcer, on the other hand, is a slowly developing chronic infection, characterized by ulceration of the skin without gangrene. It not only spreads in the subcutaneous tissues but burrows down along the muscles and along lymphatic channels, and it frequently gets into bone. When this happens it is very difficult to eradicate. It frequently erodes into blood vessels, and death may ensue from severe secondary hemorrhage. Zinc peroxide is not effective in the acute hemolytic streptococcus gangrene because the extent of inflammation in the subcutaneous slough prevents contact with the periphery of the infection. In the treatment of this disease the sulfonamides should be used in maximum doses and incision made beyond the area of subcutaneous tissue involvement, followed by treatment with diluted solution of sodium hypochlorite to aid in the liquefaction of slough. With the chronic, undermining ulcer the sulfonamides are not as effective and here the treatment of choice is zinc peroxide. The two may be combined if the drug is tolerated. If the undermining is so extensive as to prevent adequate contact with zinc peroxide, the underlying tissues must be removed by preliminary operation. Another condition which is sometimes confused with both of these lesions is the progressive bacterial synergistic gangrene, which is less acute than the hemolytic streptococcus gangrene but more rapid in its spread than the chronic, undermining burrowing ulcer. This is due, as I have shown, to the symbiotic action of the microaerophilic nonhemolytic streptococcus and *Staphylococcus aureus*.

DR LOUIS A. BRUNSTING, Rochester, Minn. In describing the character of these ulcers with their burrowing qualities and liquefying necrosis I believe the use of the term "gangrene" is justifiable. Some of the earliest descriptions of these pyogenic

ulcerations are recorded in the Medical History of the Civil War. Infections occurred at the sites of wounds and amputations in debilitated individuals under conditions of poor hygiene. The various types of gangrenous ulcerations described by Meleney and others can be made out in the earlier writings, but with the lack of present day bacteriologic knowledge there was no systematic classification. When these lesions occur in the axillas and in the region of the genitalia and the perineum they are apt to be based on the condition known as hidradenitis suppurativa. In some instances conservative treatment with the use of antiseptics and roentgen therapy is sufficient, but when there is extending infection over a considerable site it is better to excise the field and apply skin grafts. I have been interested particularly in the type of burrowing infection called pyoderma gangrenosum, which occurs chiefly in the patient who is debilitated by chronic ulcerative colitis. In those patients the bacteriologic findings are variable including either hemolytic streptococci or staphylococci or both. Many times the abscesses are sterile, especially when they occur at the site of an injection of vaccine or bruise, which leads me to believe that there is an element of hypersensitivity of the skin of such patients. As a general rule there is no response to treatment of any type unless the widespread infection in the colon is brought under control by attention to the general health of the patient. The use of multiple blood transfusions and repeated courses of the milder sulfonamide drugs is a helpful adjunct to the building up of the general resistance.

DR MORRIS H. GOODMAN, Baltimore. Ulcers of the type described by Dr. Meleney should be differentiated from an ulcer which I first described and reported in THE JOURNAL Oct. 15, 1938 with the designation chronic streptococcal ulcer of the skin. I have seen a number of cases since the date of my original report, and my observations have been confirmed by others, principally by Taylor (*ibid.*, April 4, 1942), who treated 31 cases. The lesion which I described makes its appearance following a slight injury in the form of a reddish, well defined edematous area usually on the extremities and soon ulcerates. The ulcer slowly enlarges and persists as a chronic low grade process. The borders are red and edematous and more or less tender and the edge is somewhat boggy and frequently undermined to a slight degree. The base of the ulcer shows a fairly intact granulation tissue, and a copious serous exudate is usually present. Taylor confirmed the impression that the ulcer which I described represents a distinct disease entity quite different from the chronic undermining and burrowing ulcers discussed by Dr. Meleney. Aside from a low grade transitory lymphadenitis, the ulcers of my description are uncomplicated by any systemic effects. Dr. Meleney has stated that in his cases in the early stages one recovers an aerobic streptococcus but later this organism develops anaerobic properties. In the chronic streptococcal ulcers of the skin which I described, the organism is a beta hemolytic streptococcus which is grown in pure culture under aerobic conditions throughout their entire course which ranged in duration, in 6 cases which I recently observed from three months to one and a half years. In the ulcers which I described, the use of any special local treatment is unnecessary because response to sulfanilamide, as emphasized in Taylor's report and in mine, is prompt and excellent.

DR MAURICE J. COSTELLO, New York. This patient was seen by a number of dermatologists, otolaryngologists and surgeons, all of whom failed to entertain the diagnosis as presented. The difficulty was further enhanced by the fact that this lesion occurred on the nose, which, as far as I can tell from the literature, is an extremely unusual location. Dr. Meleney has frequently stressed the importance of the early clinical recognition, confirmed by anaerobic cultures, before secondary organisms appear which make it more difficult to evaluate the role played by each. It is also important to differentiate this from tuberculosis, syphilis and carcinoma, which it simulates. Frequently the dermatologist is the first to see this type of case and I hope in the future will probably be the first one to recognize it. I thank Dr. Meleney and Dr. Brunsting for discussing this paper, and I will make the correction that Dr. Meleney referred to at the outset.

Clinical Notes, Suggestions and New Instruments

RESULTS WITH LOCAL HEATING IN PELVIC INFLAMMATORY DISEASES

CAPTAIN JOHN R. UPTON
MEDICAL SECTION AIR CORPS UNITED STATES ARMY
A. D.
CRACK HILL 50 R. P. T. T. SA. FRA. CISCO

We are presenting the results of heating tissue locally in the treatment of pelvic inflammatory diseases. The types of apparatus used consisted of the Elliott machine, the short wave machine and the conventional diathermy machine. One hundred carefully selected patients were taken for the study. The three most prevalent factors causing the pelvic conditions were gonorrhea, postabortal infections and postoperative complications. Our aim was not to 'sterilize' the pelvis of gonorrheal organisms by long continued high temperatures but to assist in the resolution and absorption of inflammatory tissue in all chronic pelvic inflammations.

Chart 1—Short wave diathermy and method. This graph shows the greatest change in temperature recorded by use of external pads. The majority of patients taking this type of treatment terminated their hour of therapy with a rectal temperature lower than that at the beginning of treatment. The recording is of a woman aged 30 whose chief complaint was pain in the suprapubic region radiating down the anterior aspects of both thighs. In 1930 an appendectomy had been performed several years later she was operated on again for the release of adhesions and a right salpingectomy and puncture of bilateral cysts on ovaries were executed. The diagnosis was extensive postoperative adhesions. Results from the diathermy were quite good. Relief from pain and a much freer pelvic cavity resulted. The patient was last seen in August 1938.

Chart 2—Results of sixteen successive treatments with short wave diathermy and method. These were carried out on the patient described in chart 1. If as is generally thought a moderately high temperature plays a dominant role in the treatment of an inflammatory disease of the pelvis then this patient derived little benefit. The clinical result however, was satisfactory as has been pointed out.

The principal aim of any piece of therapeutic apparatus is to attempt to heal tissue and not to kill it or render the cells incapable of regeneration from disease processes or of further physiologic growth. Roentgen rays if improperly used are capable of irreparable damage to tissues, but placed in competent hands they are of inestimable value. The same is true of diathermy.

For the sake of brevity, the charts will show the results obtained and the comparisons between the three methods used. In the evaluation of such records many facts must be sifted and segregated. Several histories were excluded from this study because in our opinion the diagnosis was incorrect. For example, a woman had a retrodisplaced uterus in the third degree position. When we examined her after her first treatment we were able to bring the uterus into position quite readily, and with the help of a pessary an excellent result has been obtained. Naturally we feel that this case and similar ones should not be included in the small series presented here.

Surgical intervention is still the only method used to eradicate the results in all too many women who show pelvic disorders as the aftermath of some infection. We cannot stress too strongly the fact that if surgery only has been resorted to then the best interests of the patient have not been served. Quite frequently when a younger woman has been operated on for the usual pelvic sequelae of a gonococcal infection, the surgeon must of necessity remove several structures which are necessary to the generative system, and frequently a "clean sweep" is the result. Once tubes or ovaries are removed, the woman becomes barren so far as the reproductive phase is concerned. This is a particularly significant fact when we say that the great majority of our patients were under 30 years of age, i. e., in the full maturity of their reproductive cycle. This should clarify the allocation of responsibility, for if the age group fell more closely to the menopausal line there might be more reason for an operative termination of the processes of the pelvic disorder. However, we are still faced with the painful truth that the majority of these pelvic conditions are the result of a gonorrheal infection and that the highest incidence for this infection falls between the eighteenth and the twenty-fourth year. Our duty is quite clear. We should constantly seek to eradicate the inflammatory infection due to some youthful indiscretion on the part of the female and still try to maintain the reproductive processes intact, so that fertilization may later ensue and a healthy baby and mother be the ultimate happy outcome. The other two causal agents

infectious process must all be evaluated. The threshold for pain tolerance likewise varies considerably in different women. However, we believe that, other factors being equal, we obtain better results when the pelvic cellular reaction is minimal even though the pain experienced may be severe. The greater the inflammatory masses present, the longer time performance must

Chart 4—Elliott treatment. A more pronounced temperature rise is seen than in the preceding charts with other methods. Frequently, however, the treatments had to be postponed because of vaginal burns sustained during the administration. If a bubble of air becomes trapped in the rubber applicator owing to the necessary manipulation incident to the pressure and suction changes the chances of the underlying vaginal tissue sustaining a burn are increased. The method is not so easily carried out as with the conventional diathermy and certainly more pain is experienced by the patient. Patients with intact hymens are unable to take this form of therapy. End results generally were satisfactory.

First treatment 30 minutes only

that make up the impressive triad responsible for so much pelvic trouble are postoperative adhesions and disorders and postabortal complications.

The degree and extent of a pelvic inflammation appears to have little relationship to the pain suffered. Quite frequently a woman presents a pelvis filled with inflammatory masses and yet does not complain of severe discomfort, while some

Chart 3—Short wave diathermy, cable method. The cable was spaced completely around the pelvis. Patients taking this type of treatment complained about the generalized heating of the body. A woman aged 23 whose temperatures are charted had been subjected to three operations. An appendectomy was performed in 1937, a sinus tract which developed was explored several months later and in 1938 a pus sac in the pelvis and the sinus tract were removed. The left ureter was constricted by the inflammatory mass and a hydroureter resulted. The diagnosis was massive postoperative and infectious adhesions and the development of a hydroureter on the left side. The patient was discharged from the gynecologic and genitourinary clinics after twelve treatments and has not been seen for four months.

slight motion to the cervix in another patient showing very little reaction causes decided pain. Different causative invading organisms, different sites attached and different stages of the

the diathermic measures be continued. Absorption and resolution of exudate takes time, and if there is a purulent condition present the time factor will of necessity be prolonged. However, the presence of accumulations of pus in the pelvis does not contraindicate diathermy and certainly does not presage a failure for the method. An acute abscess in the cul-de-sac is treated best by colpotomy drainage. As a general statement we can say that our results show that postabortal and gonorrheal infections do remarkably well under diathermy but that postoperative complications do not respond so readily.

One must be on guard for evidences of psychic trauma in women presenting pelvic symptoms. Particularly is this mental imbalance seen in the postoperative patients who have not been aided by the first operation. Several patients in our small series have had notations made in their charts by the psychiatrists to the effect that further surgical intervention might have a permanent effect on the already imperfectly functioning nervous system. We have all seen women who constantly besiege the doctor to operate on them when their real complaints might better have been dispelled by a psychiatrist. Our modern, complex, rapidly moving environment takes its toll of human economy and women frequently show their disharmony to this rushing age by vague pelvic distress. The uncertainties of wartime, with the resultant disruption of family life, has now imposed a further strain on the human system.

There are many men who would withhold diathermic measures in chronic conditions of the pelvis and would use it only in cases of subacute involvement. We know that many

chronic disorders of the pelvis have been aided materially and we have seen some old infections literally melt away under treatment. Clinically, however, the chronic condition is more stubborn of cure than the subacute, and a longer series of treatments must be anticipated. Some patients, it is true, cannot be helped at all, and it is these who must derive aid from surgery.

Chart 5—Elliott and vaginal diathermy. This graph shows the average temperature of a patient who pre-entered her self with a subacute vaginal gonorrheal infection. The Elliott machine was used first and then vaginal diathermy was used for the second series of treatments. There is a difference of approximately 2 degrees centigrade between the two methods. Asked which treatment she preferred she emphatically declared in favor of the vaginal diathermy. The clinical response to the Elliott machine was excellent for a while but later on hydrophilus developed on the left side which under the vaginal diathermy responded extremely well. To date she has been free of symptoms.

Such important details as building the patients up physically so that the tired bodily defenses can best take advantage of the assistance offered should really not need stressing, but most of the patients with such infection fall in the poorly nourished stratum of society, and their resistance is quite low. In most instances it is found that there are several unrelated factors, all of which tend to provoke and aggravate the debilitated state of the patient. The most frequent conditions encountered outside of the pelvic infections proper were abscessed teeth, infected tonsils, chronic constipation, varicose veins, visceropelvic malnutrition, poor posture, anemia and various stages of an-

Chart 6—Vaginal diathermy showing the average temperatures obtained. Vaginal, rectal and mouth temperatures were recorded. Treatment by this method was smooth with only an infrequent complaint being made about the treatment causing vaginal pain. There was a local sensation of warmth as contrasted with a generalized sense of heat when the short wave pad or cable was utilized. In treating 58 women with this technique we had 10 clinical failures 6 for postoperative complications. Forty of the 58 patients were definitely helped by the treatment and 24 showed a decided decrease in the size of the pelvic inflammatory exudate. There were 8 clinically cured (the criterion being complete absence from pain and a pelvis free from inflammatory exudate). Of these 8 only 1 had a postoperative complication. Four women became pregnant and carried safely through to term and delivered without mishap.

tamnosis. We firmly believe that a complete general examination is imperative, for only by irradiation of such nagging conditions and foci of infection can one hope to obtain amelioration of the larger issue. Chemotherapy, referring particularly to the sulfonamide derivatives should be adequately used, occasions arise in which these drugs can be used to advantage during treatment by diathermy.

The accompanying graphs represent a composite picture of the patients treated. The women were attended by the same technician (G. B.), so that uniformity of treatment was established and a more accurate check made possible. Follow-up examinations were likewise made by one of us (J. R. U.), and progress notes were standardized as far as possible.

SUMMARY AND CONCLUSIONS

- 1 Local pelvic heating should be used more extensively in the treatment of subacute and chronic pelvic inflammatory diseases.
- 2 Surgery should be withheld until more conservative measures have been given a trial.
- 3 The ideal outcome would be complete absorption of the inflammatory tissue leaving the patient capable of reproduction and able to carry through to term.

Chart 7—Composite set of graphs illustrating the greatly varying range of temperature readings obtained by the use of the preceding method and in addition by the use of the short wave cable in the form of a pancake on the abdomen.

- 4 The best clinical results were obtained with the conventional diathermy for which the vaginal electrode was used.
- 5 The best clinical results were obtained when a moderately high temperature was sustained.
- 6 Short wave diathermy with the vaginal electrode gave equally good results. Fair effects were noted with the pad or coil method.
- 7 We encountered a number of vaginal burns when the Elliott machine was used.
- 8 Skin tolerance to diathermy appears still to be the best indicator in preventing damage to the tissues.
- 9 Gonorrheal and postabortal infections respond more readily than postoperative complications. No attempt was made to kill the gonococcus in any of our cases in which local protracted high fever therapy was given.
- 10 Psychic factors must be closely evaluated in women complaining of pelvic discomfort.
- 11 Noteworthy features of conventional diathermy are ease of treatment, local as contrasted with a generalized heating much more comfort for the patient, relief from pain decrease in size of inflammatory exudate, less chance of damage to

issues, fewer treatments necessary and possibility of fertilization at a later date is contrasted with the usual operative barrenness when surgery is resorted to

CAUTION

The federal law requires all persons using short wave diathermy apparatus to register their equipment with the local authorities. This is a war measure.

PNEUMONIA CAUSED BY MICROCOCCUS TETRAGENUS

WALTER R. TOBIN, M.D. CHICAGO

The organism *Micrococcus tetragenus* was first described by Koch¹ and Gaffky² in 1881. It is commonly found in long standing progenic processes in association with a variety of other organisms and in this connection is thought to be a secondary invader and a saprophyte. It has also been reported frequently as a primary cause of infection in various parts of the body, such as meningitis, otitis media postpartum infections, acute endocarditis, septicemia and arthritis. A search of the literature, however, failed to find this organism attributed to the cause of pneumonia except in 3 instances all of which were reported in foreign literature. The following is a brief summary of these cases.

Delearde³ in 1897 reported in detail a case of bronchopneumonia due to *M. tetragenus* in a man aged 49. He recovered the organism in great abundance in practically pure culture. He made note that the disease was severe and characterized by repeated chills. The patient survived but remained in the hospital for six weeks. Castaigne⁴ in that year also identified *M. tetragenus* in a case of pleurisy with effusion, but no mention was made of pneumonia.

Bosc⁵ in 1900 reported a case of suppurative bronchitis and bronchopneumonia in a 21 year old patient with autopsy findings. *M. tetragenus* was recovered from the bronchial secretions in pure culture. This patient also had enterocolitis and suppurative peritonitis at the time of death and these processes also yielded pure cultures of this organism. Detailed description with illustrations are given embracing the gross and microscopic as well as the bacteriologic aspects.

Byers and Houston⁶ in 1913 described a case of severe bronchopneumonia in a 10 year old child that followed in the wake of a comparatively mild infection of the middle ear and upper respiratory tract. Cultures made from the sputum, pharynx, ear discharge and urine were of a mixed variety, but in each case colonies of *M. tetragenus* were found. *M. tetragenus* grew from the blood in pure culture. They concluded that this organism was the cause of the pneumonia and not others that were found in the sputum, because the patient's blood gave a high opsonic index to this organism and not to the others as compared to normal blood serum, also because an autogenous vaccine prepared from the cultures of this organism injected subcutaneously gave a pronounced reaction even in small doses and had a decidedly favorable effect on the clinical course of the disease, whereas a stock vaccine previously administered gave neither reaction nor therapeutic response.

The case presented here was considered worth reporting because the organism was isolated from the sputum, blood and urine early in the disease in pure culture, and because the disease was otherwise uncomplicated.

From the Department of Northwestern University Medical School. The case reported here was referred to the author by Dr. Stanislaus Novak.

REPORT OF CASE

Mrs. S. M., aged 43, a housewife, had a mild chest cold for about a week and on May 28, 1941 entered the hospital with symptoms of chills, fever, pain in the chest and vomiting. Her temperature was 103.4 F., pulse 126 and respiratory rate 40 to 46 per minute. The white blood count was 13,450 with 96 per cent polymorphonuclear neutrophils. The red cell count was 3,370,000 and the hemoglobin 11 Gm. per hundred cubic centimeters. She appeared very ill and was mildly cyanotic. No definite consolidation was found, but the breath sounds were impaired. Moist rales were heard scattered over the lower half of both lungs, anteriorly and posteriorly. A diagnosis of bronchopneumonia was made and confirmed with x-ray examination. After several unsuccessful attempts to obtain sputum for analysis, a specimen was recovered by means of a tracheal catheter. The cytologic examination of the sputum thus obtained revealed only cocci, few in number, which were not characteristic of pneumococci and did not show capsular swelling by the Neufeld method. Culture of this specimen resulted in the abundant, almost pure, growth of an organism which proved to be *Micrococcus tetragenus*. A blood culture, taken on entrance to the hospital, revealed the same organism. A few days later the patient complained of frequency and burning of urination, and examination of the urine showed 50 to 100 pus cells per high power field. A pure culture of *M. tetragenus* was also made from a catheterized specimen of urine. In order to confirm our contention that *M. tetragenus* was the responsible organism repeat cultures of the blood, urine and sputum were made and in all 3 instances the results were

Temperature during the second week of the disease showing malaria like record

identical. The sputum was examined for acid fast bacilli, but none were found. The blood Wassermann and Kahn reactions were negative.

The course of the illness was stormy, characterized by repeated chills every one to three days, which were followed by an increase of fever, up to 103 or 104 F. Sulfapyridine was administered by mouth in doses varying from 1 to 2 Gm. every four hours, which maintained the blood level at 9.5 to 11.5 mg. per hundred cubic centimeters. The drug, as is reflected in the temperature curve, appeared to have little effect on the course of the disease. For one forty-eight hour period sulfathiazole was substituted for the sulfapyridine without obvious clinical change in the patient. Potassium iodide was administered by mouth for its supposed effect in disintegrating the capsule, but without effect. Other standard therapeutic measures used consisted of oxygen, frequent blood transfusions, adequate caloric intake, sedatives and the maintenance of water, electrolyte and vitamin balance. Vaccine therapy was not tried. Recovery was gradual and the patient was discharged from the hospital June 22, twenty-five days after entrance.

SUMMARY AND CONCLUSIONS

A case of bronchopneumonia complicated by bacteremia and urologic infection was due to *Micrococcus tetragenus*. Sulfonamide derivatives in this case failed to produce a therapeutic response. In view of Byers and Houston's report of successful treatment of a similar case with an autogenous vaccine it would seem advisable to give this method a trial when other readily available measures have failed.

Special Article

HANDBOOK OF NUTRITION XX

FEEDING THE AGED

EDWARD L. TUOHY, M.D.
DULUTH, MINN.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

At the outset I present five reasons why practicing physicians should become interested in the problem of feeding the aged. When they convince themselves that overindulgence and needless restriction in food are both wrong, then will their patients gradually conform. They always have conformed and on many occasions have accepted guidance far less scientifically sound than that outlined in this series on nutrition.

1 Those living over 60 are now so numerous that their individual needs call for an active aggressive medical approach. The individual, instead of his disease is our problem. We must become guides or umpires rather than healers and on a long term, rather than a temporary, basis.¹ The treatment of diabetes with balanced diets and insulin, of pernicious anemia with liver extracts, illustrates the technique. We have asked repeatedly that we be allowed to keep the "physician-patient" relationship. Here is our opportunity.

2 Mass efforts (for preventable diseases) and specifics (for certain infections) have nearly eliminated many common diseases (diphtheria, typhoid). We are on the way to control pneumonia if seen early. Less young people die, more attain advanced age unhampered by a holdover of morbidity from earlier nonfatal encounters that nevertheless leave their scars.

3 The competence of healthy older people is largely a matter of nutrition. Doctors also have an age problem. They also age. America is at war. There is no turning back. Physicians attain their fourth decade before they become active in their respective fields. They need more years of activity after 60 than most are favored with. Coronary disease is all too common with doctors. I shall refer to it at some length because food excesses (fat) may be a factor involved.

4 Population is an asset. Human beings must never be classed as liabilities. Guiding the aging may be made a stimulating medical field. It is not a "second childhood" affair, as the uninformed facetiously imply. Geriatrics is less a science than an art. It is not an isolated specialty comparable to pediatrics. The pediatrician tells the mother or nurse what to feed the child. If the food is available, the child usually gets it. The geriatrician (I do not aspire to be one) usually finds his older subjects neither acquiescent nor especially cooperative. Food habits have become fixed, those

under or over eating enjoy their self determination. Accordingly it is not sufficient to tell off average menus suitable for the old. This simple assignment I leave to the scores of available diet manuals. Some argument must be presented to give the whys and wherefores of the need of balance in various foodstuffs and vitamins. The overrefinement of starch and excessive use of sugar must be warned against and the reasons made clear enough so that appetite is not the sole guide to eating. All specialists and general practitioners giving service to the old should familiarize themselves with the researches in nutrition now contributing so effectively where understood and applied.

I shall attempt to assemble the evidence establishing adequate nutrition as the present day primary need of the older age group. The previous chapters in this series have authoritatively outlined the increment in knowledge of nutrition that has come since the turn of the century. McLester in the introductory chapter expressed the fear that, despite all these advances there may follow an undue lag before this nutritive beneficence becomes a part of our life and heritage. It rests with practicing physicians to limit this lag, to bring about within as few decades as possible (especially for the older age group) something comparable to the improvement in nutrition that has already come to two generations of babies since pediatricians have put the balanced nutrition into effect.

5 We have the present war emergency. There is much salvage within the old age group. No portion of the present nutritional program should be denied the aged on any basis dictated by their years. Age is hard to define. It is known best by what it does. It limits outlook and capacity; it adds its aches and qualms; all too readily attributed to ingested food. The food left out may contain the elements that complete the vicious circle so that less food, more infirmity, more symptoms, less efficiency pile up. Age conceals a vast reservoir of talent, skills, wisdom and experience, not to mention much muscle and brawn if proper food maintains reserve. There could not be a better time to plan a purposeful nutritional program for the peace that must follow war. Doctors must take part in it.

This is a machine war—the product of a machine age. In our depression years unemployment, broken homes, improvident children, impractical subsistence relief or pensions, robbed the old of employment position, honor and a place in the community. With such crying need for all possible man and woman power it is now or never for us to give back to this group some of what they have lost.

THE EXTENSION FOOD AVAILABILITY EMPLOYMENT

Life extension has brought great social and economic problems (table 1). I shall add but few of the figures now so freely quoted. The most striking prediction concerns that "22,000,000 people in the United States over 65 years of age" within another generation. Up to the time of our engagement in the war efforts and for ten previous depression years, youth was held back from production. Those discharged over 50 found industry hesitant to reemploy them. Now we face a condition where retirement after 65 promises less and less as taxes and living costs mount as investment possibilities narrow and pensioners multiply. In the offing there is always the specter of inflation. At present few people think of leisure or retirement, it is timely to

¹ The only chronic malady showing striking decrease is tuberculosis.

emphasize the great advantage of cultivating health, mental poise and technical skills and avoiding obsolescence. Since the turn of this century the life expectancy of white babies has been advanced sixteen years for females and fourteen for males. This totals up to 67.31 for the former and 62.94 for the latter. The immediate and pressing issue is: How may these years be made worth while? Food is a basic requirement, the amount and proportion depend on the individual and where and how he lives. It may be said, with few exceptions, that to deny people work is to deny them food. Now, when production is so much in the forefront of our national demands, we must salvage everything possible, and certainly not the least item in this effort is the group concerning which I write. If justice is ever to obtain, the appeal "Give us this day our daily bread" must exclude none. The way to give it is to plan that all able shall work, doles and subsistence are mockeries. This is a peace program with which a war schedule must be implemented. Otherwise we shall still be at war, for with the military peace we shall continue economic war.

THE FALLACY OF FOOD RESTRICTION FOR THE AGED

A stupendous literature dealing with nutrition accumulates. I append references to certain authors where some may wish to know the source material. The resurgence of interest in dietetics has come at the same time with a reviving interest in medical geriatrics. Many² have written articles based on the medical needs of the aged. There is a new edition by Thewlis³ bringing up to date the pioneering of Nascher, a recent handbook by Boas⁴ dealing with the treatment of the patient after 50 is well arranged and documented, and considerable attention is paid to diets. Cowdry's⁵ compendium from various authors, including physiologists, biochemists and psychologists, is most readable and informative. Some readers will be displeased that so few positive factual statements may be made. People around the world live well on the most varied diets, each satisfactory as decreed by custom and availability. If the reader would like an American menu for elderly people, there are available countless articles where these may be consulted and individual tastes consulted. Some statements might be "factual" if more were known about aging as a process.

For reasons hard to understand there is the widest belief that the elderly should be abstemious. The few gluttonous and obese have visited this inhibition on the many who are overconscientious and underweight. We should start with the dictum of Piersol and Bortz⁶ "To add life to years rather than years to life." That is the basic motive for campaigning for better nutrition

for the aging. What we are looking for is not a dragging out of vegetative almshouse existence but the promotion of real efficiency. The human being attains his full bodily development, let us say, by 40, the beginning of his fifth decade. His next decade and a half pits him against the most stressful period of his life: the time in which early rheumatic and other infections mature and cripple, when arterial hazards (coronary disease) add their tragic interruptions, when metabolic perversions (obesity, diabetes and gout) appear—all when his business, his insurance plans, his educational and family responsibilities are at their height. And this is the period when we ask him to prepare himself for the seventh, eighth and ninth decades which present life extension tables plainly tell him are "just around the corner." This is no longer a promise or objective, it is with us here and now and in very formidable proportions. Dominant as heredity is known to be, we may just as well leave it out of the discussion. Each individual must accept the genetic complement fate has assigned him. He must make the most out of what he has. It must be clear that no one may expect the most from the later age decades when no preparation has been made in adjusting habits, cultivating something of a philosophical attitude toward life and its respon-

TABLE 1—Age Level Extensions*

	1900	1937	1940
Average age at death	26.79†	58.60	62.00
Death under 1 year	24%	5%	5.2%
Death over 70	4%	20%	32.1%
Death at 45 or over	24%	79%	83%

* Statistics furnished through Dr. Mario Fischer, Duluth Health Commission.

† There was at that time a high death rate from typhoid and tuberculosis as well as from complications of all the contagious diseases of childhood. In the summer time there was the traditional high death rate from feeding disturbances in children and pneumonia was prevalent in the winter. Many woodsmen and miners came into Duluth for terminal hospitalization.

sibilities and at least looking about among friends and neighbors for object lessons or examples of men and women who are succeeding in various stations and walks of life in arriving at what we call a comfortable and serene old age. Age is feared much more for the restrictions it may impose than the promise of death. The body as well as the mind must be trained to accept aging. The time to acquire the physical and mental deportment with which to get the most out of life in its later decades is in middle age. The neurosurgeon cannot acquire his skill for the successful removal of a brain tumor when the patient with a terrific headache enters his consulting room. The cultivation of proper food habits early in life is too obviously advantageous to call for further discussion or elaboration. We must learn to grow old skilfully as well as gracefully.

Perhaps "the less food for old people" fallacy hinges on the supposition that for them energy for current expenditure is the chief item and therefore carbohydrate and some fat with a minimum of protein suffice. In any case, that is the way many old people exist but do not live. All living creatures are interrelated and follow universal laws in their metabolism and growth. Life and its products are handed back and forth between living creatures (plant and animal). Nature has provided these laws of balance and coordination. Simpler organ-

isms accept them, but man has varied notions of his own. He chooses primitively with the least cultivated of his tastes. The result is a diet over-rich in refined flours and sugar. He misses the balanced assemblages plant life has integrated and domestic animals have concentrated for him. They do it better than he can plan it. Hence the appeal for natural foods, including animal products. Human growth is not terminated when adult stature is attained. Witness the manner in which the atrophic smooth tongue of Addisonian anemia assumes normal size and coating after optimal exhibition of liver. The Lawrences have shown with Geiger counters how rapidly tagged iodine is picked up by the thyroid. Tagged calcium has been located promptly in tooth enamel, long supposed to be fixed, inert and final for the duration of life. Rates of growth vary, but the process endures with life. Repair within the body is a continuous process and in such organs as the liver may be stupendous. Fixed and overspecialized cells (retina) must also be undergoing some change, as is disastrously connoted when the blood supply is even temporarily interrupted. In that sense reproduction of the individual as a unit is limited by age, but, in the cellular domain, active living processes demand nitrogenous equilibrium continuously. The tea and toast schedule for grandma is outmoded. No old person is a walking museum piece—a holdover from last year's crop—and for the same good reason must not be treated like a barnacle on the ship of state.

Stieglitz⁷ has used the term gerontology to cover a study of the aging process, in contrast to geriatrics (care of the elderly). The distinction is proper. Simms⁸ has studied Dublin's insurance mortality records and computes that our young adolescent at age 10 is the healthiest human being only one in eight hundred dies at that age. He states that if such a mortality were maintained the life span would stretch out to 550 years.¹ Age, as a name for what Shakespeare meant when he wrote "We ripe and ripe and ripe, and then we rot and rot and rot," while indeed baffling to scientists, is very obvious to women of fashion. They are most familiar with what age does to the skin. Roger Bacon thought age concerned the withdrawal of water from the body and was in the nature of wilting. He was well informed, fluid balance connotes integrity. To the three great reserve organs of the body—the liver, the muscles and the skin (commonly listed)—I would presume to add the osseous system, not only for its calcium reserves, but for the housing of the important areas of hematopoiesis. Cannon ventures a practical explanation of age without entering into the chemist's discussion on collagen metamorphoses, he says age witnesses a gradual limitation of homeostasis wherein such body constants as acid-base equilibrium, body temperature, mineral and water balance are still maintained but within progressively narrowed limits. Physiologists strive to produce in animals counterparts of the human diseases they are studying. I was surprised in my reading to learn that not a little research has been done with the lower animals on the problem of age. Simms⁸ has made a plea for much greater financial support for research along the lines of deter-

mining how age limits physiologic responses. This is directly in line with Stieglitz's⁷ gerontology. Simms has developed a method of sublethal bleeding of standardized rats of various ages. The older rats stood the shock (Cannon-Blalock) of this bleeding with "a probability of death sixteen times greater than with the younger rats." Dearing,⁹ experimenting with digitalis and its toxic effect on the heart, brain and coronary blood flow, found that his older animals did not withstand the drug nearly as well as the younger. One turns from these laboratory experiments to the obvious deductions of the sports writers. The prize fighter is out by age 30, the baseball player by 35, and now we are told that, to meet the demands of the "blackout" incidental to dive bombing, only the youngest aviators are able to withstand this rigorous test. Fulton¹⁰ has written on the "acceleration factor," the mechanical process by which the swerving plane drives the blood centrifugally so that the flow does not accommodate rapidly enough to the change of direction of flight so that blood attains the higher centers. So the youngest and sturdiest are chosen to sustain these enormous stresses because they better retain consciousness.¹¹ Youth is able to establish records in the shorter sprints and hurdles, but when prolonged effort is displayed (distance runners, sand hog workers) older men have an advantage accruing from skill and husbanding their strength. Industrialists should remember this. Freeman¹² and others studying shock, stress the factors of exposure, cold fatigue, blood loss and water loss. Shock is in part, an exaggeration of situations beginning as discomforts and mounting to dire upsets of homeostasis and challenging the integrity of the individual by dissociating the orderly functioning of system organs. Elderly people have simpler names for chills, fatigue and exhaustion. Food and drink exhilarate as does nothing else. Add sleep and you have recuperation. Periodic starvation has no place in the care and conditioning of the old and is one of many useless middle age fads. This is the background for practical suggestions I shall make in terms of when and what to eat.

FOOD AND THE CARDIOVASCULAR SYSTEM

"A man is as old as his arteries." This statement has been too long accepted by clinicians. We look at an older person and then palpate the peripheral arteries. "Peripheral vascular disease" is a category that covers many difficulties experienced by the aged. Certain chapters in Cowdry's book discuss a dissociation of aging and arteriosclerosis—the former a natural process beginning before birth, the latter an unnatural requisition so common that many think it universal. We face a medical problem when many in the prime of life die with 1 centimeter or less of thrombus in the branch of an atheromatous coronary artery, while many octogenarians are hale and hearty with most of their larger arteries laid down in concrete. Wherein does the question of diet enter into this discussion? Is aging hastened

by overeating? Does abstinence promise a long life? The answers to these and many similar questions are not forthcoming but the statement by Simms that many useful years may yet be added through life extension when science discovers how to prove the aforementioned dissociations and produce specific inhibitors points the way. In the meantime we may learn something by looking about us and, while clinical observations may be loose and indefinite, Spies has significantly commented that our knowledge of the avitaminoses has been substantially advanced by such observations and by testing out the newer pharmacutic vitamins and ordering better foods.

There is also considerable difference of opinion as to just how much over or under nutrition exists in our country, in different states and among different classes of people. Chapter XXII (Sticbeling) will discuss that issue based on her extensive observations and studies in association with the United States Department of Agriculture.¹³ I think undernutrition produces more physiologic disturbances, but overnutrition (fat) may hasten the development of more pathologic change.

Living in a rich agricultural state, I do not see very many people needlessly undernourished. By proper planning and marketing and with attention to the methods discussed in chapter XVI (Cowgill) most of the borderline or marginal degrees of undernutrition which we uncover are economically unnecessary and stem from social maladjustment, anxiety states and outmoded medical advice. Undernutrition reduces vitality and well-being much more than it hastens decline or senility. It is hard to believe that "optimum nutrition" could endanger anybody's vascular system. The trouble lies in finding an "optimum diet"—because it varies with every locale, every people, employment and individual purpose, and nature has distributed around the world the widest assortment of adequate food sources. Some may like a "short life and a merry one"—at least at middle age that is their choice. Whatever the process by which it is brought about, 70 per cent of our Duluth Clinic¹⁴ patients are dying of cancer and cardiovascular-renal disease (including cerebral hemorrhage). This figure for cancer (18 per cent) is higher than the Minnesota State Board of Health figures (14 per cent) for 1941 and represents a higher than average of older people in our clientele. The approximate 50 per cent of cardiovascular renal disease¹⁵ is the same as Simms's claim for all deaths over age 10. I have checked these figures from four old line life insurance companies, and I present in table 2 the results from one of them. The others are almost identical. This detail of end results tells little, of course, relative to incapacity and sickness among the group I am discussing. From many studies dealing with the prognosis in degenerative heart disease it would be fair to state that there is an average illness (partial or complete) of about two years. During that time diet is a part of the treatment and is subordinated thereto. Unless some newer food components (biotin) can be proved to be carcinogenic, preventive measures (diet) in terms of about three fourths of our deaths are very much in that current state of "too

little and too late." Table 3 shows clearly enough that the life line of our people is rather well extended. It prompts me to add "I should tell them how to eat and how to spare their arteries!"

THE SOCIAL AND ESTHETIC ASPECTS OF EATING

No discussion on the subject of diets for the elderly should leave out some tribute to food based on values other than its caloric content. Religious, national and family feastings on holidays have been such a civilizing influence that any campaign for better nutrition must never overlook the spiritual and social resources arising from the table or the sharing of food. While vacillating between the dangers of undereating and overeating (a fair optimum diet) I must not appear to condone the gourmand. Women are much more susceptible to food faddisms than men, and fashion is apt to dictate the basis on which many digestive neuroses develop. Dorothy Dix avers apropos of woman's destiny, "They seem either to become skeletons or feather pillows." It is either a "feast or a famine" with all too many people. Prentice shows that that is history.

TABLE 2—Causes of Death*

	Year		
	1941	1931	1921
Circulatory diseases (heart disease, apoplexy and so on)	42.2%	32.8%	25.4%
Cancer and other malignant tumors	10.1	10.2	10.6
Violent deaths (automobile, suicide, aviation)	9.4	10.9	14.1
Respiratory diseases (tuberculosis, pneumonia, influenza)	8.6	14.6	19.3
Digestive and genitourinary diseases (diabetes, nephritic, ulcer, liver)	7.6	12.2	15.9

TABLE 3—Cardiovascular Deaths in Minnesota for 1940

Total for such deaths	7,693
Rate per 100,000	275.5
60 years and over	79.5%
80 years and over	24.7%
Deaths certified from	
Myocardial disease	25.4%
Coronary disease	33.6%
	64.0%

repeating itself. Hunger is a natural instinct with the young, it is often a luxury with the old. Food must be made attractive. The atmosphere should be conducive to liveliness and some approximation of what Edwin Markham calls man's primary needs: bread, brotherhood and beauty. We need a modern Brillat-Savarin¹⁶ with ability to popularize the nutritional nuggets today's science provides us in the manner in which he popularized esthetic living and dining.

PRACTICAL GUIDANCE

1 *Protein* (chapter II, Lewis)—The need of protein at all ages is now so well established that little argument need be advanced. A few simple statements for the unconvinced should suffice. Note how the "essentialness" of the amino acids keeps step with the components of B complex and B₁. I wish especially to illustrate the significance of the liver in homeostasis. Goldschmidt, Vars and Ravdin¹⁷ noted the liver pro-

13 This department publishes a long list of studies full of interest and information.

14 This study is part of a sampling of our records with especial reference to the deaths. For the year 1940 and 1941 1,339 deaths have been carefully traced covering patients of all ages whom we have seen since 1915.

15 This is the group in which gerontologic research may be most productive (Simms).

isms accept them, but man has varied notions of his own. He chooses primitively with the least cultivated of his tastes. The result is a diet over-rich in refined flours and sugar. He misses the balanced assemblages plant life has integrated and domestic animals have concentrated for him. They do it better than he can plan it. Hence the appeal for natural foods, including animal products. Human growth is not terminated when adult stature is attained. Witness the manner in which the atrophic smooth tongue of Addisonian anemia assumes normal size and coating after optimal exhibition of liver. The Lawrences have shown with Geiger counters how rapidly tagged iodine is picked up by the thyroid. Tagged calcium has been located promptly in tooth enamel, long supposed to be fixed, inert and final for the duration of life. Rates of growth vary, but the process endures with life. Repair within the body is a continuous process and in such organs as the liver may be stupendous. Fixed and overspecialized cells (retina) must also be undergoing some change, as is disastously connoted when the blood supply is even temporarily interrupted. In that sense reproduction of the individual as a unit is limited by age, but, in the cellular domain, active living processes demand nitrogenous equilibrium continuously. The tea and toast schedule for grandma is outmoded. No old person is a walking museum piece—a holdover from last year's crop—and for the same good reason must not be treated like a barnacle on the ship of state.

Stieglitz⁷ has used the term gerontology to cover a study of the aging process, in contrast to geriatrics (care of the elderly). The distinction is proper. Simms⁸ has studied Dublin's insurance mortality records and computes that our young adolescent at age 10 is the healthiest human being—only one in eight hundred dies at that age. He states that if such a mortality were maintained the life span would stretch out to 550 years! Age, as a name for what Shakespeare meant when he wrote "We ripe and ripe and ripe and then we rot and rot and rot" while indeed baffling to scientists, is very obvious to women of fashion. They are most familiar with what age does to the skin. Roger Bacon thought age concerned the withdrawal of water from the body and was in the nature of wilting. He was well informed, fluid balance connotes integrity. To the three great reserve organs of the body—the liver, the muscles and the skin (commonly listed)—I would presume to add the osseous system, not only for its calcium reserves, but for the housing of the important areas of hematopoiesis. Cannon ventures a practical explanation of age without entering into the chemist's discussion on collagen metamorphoses, he says age witnesses a gradual limitation of homeostasis wherein such body constants as acid-base equilibrium, body temperature, mineral and water balance are still maintained but within progressively narrowed limits. Physiologists strive to produce in animals counterparts of the human diseases they are studying. I was surprised in my reading to learn that not a little research has been done with the lower animals on the problem of age. Simms⁸ has made a plea for much greater financial support for research along the lines of deter-

mining how age limits physiologic responses. This is directly in line with Stieglitz's⁷ gerontology. Simms has developed a method of sublethal bleeding of standardized rats of various ages. The older rats stood the shock (Cannon-Blalock) of this bleeding with "a probability of death sixteen times greater than with the younger rats." Dearing,⁹ experimenting with digitalis and its toxic effect on the heart, brain and coronary blood flow, found that his older animals did not withstand the drug nearly as well as the younger. One turns from these laboratory experiments to the obvious deductions of the sports writers. The prize fighter is out by age 30, the baseball player by 35, and now we are told that, to meet the demands of the "blackout" incidental to dive bombing, only the youngest aviators are able to withstand this rigorous test. Fulton¹⁰ has written on the "acceleration factor," the mechanical process by which the swirling plane drives the blood centrifugally so that the flow does not accommodate rapidly enough to the change of direction of flight so that blood attains the higher centers. So the youngest and sturdiest are chosen to sustain these enormous stresses because they better retain consciousness.¹¹ Youth is able to establish records in the shorter sprints and hurdles, but when prolonged effort is displayed (distance runners, and hog workers) older men have an advantage accruing from skill and husbanding their strength. Industrialists should remember this. Freeman¹² and others studying shock stress the factors of exposure, cold, fatigue, blood loss and water loss. Shock is in part, an exaggeration of situations beginning as discomforts and mounting to dire upsets of homeostasis and challenging the integrity of the individual by dissociating the orderly functioning of system organs. Elderly people have simpler names for chills, fatigue and exhaustion. Food and drink exhilarate as does nothing else. Add sleep and you have recuperation. Periodic starvation has no place in the care and conditioning of the old and is one of many useless middle age fads. This is the background for practical suggestions I shall make in terms of when and what to eat.

FOOD AND THE CARDIOVASCULAR SYSTEM

"A man is as old as his arteries." This statement has been too long accepted by clinicians. We look at an older person and then palpate the peripheral arteries. "Peripheral vascular disease" is a category that covers many difficulties experienced by the aged. Certain chapters in Cowdry's book discuss a dissociation of aging and arteriosclerosis—the former a natural process beginning before birth, the latter an unnatural requisition so common that many think it universal. We face a medical problem when many in the prime of life die with 1 centimeter or less of thrombus in the branch of an atheromatous coronary artery, while many octogenarians are hale and hearty with most of their larger arteries laid down in concrete. Wherein does the question of diet enter into this discussion? Is aging hastened

by overeating? Does abstemiousness promise a long life? The answers to these and many similar questions are not forthcoming but the statement by Simms that many useful years may yet be added through life extension when science discovers how to prove the aforementioned dissociations and produce specific inhibitors points the way. In the meantime we may learn something by looking about us, and, while clinical observations may be loose and indefinite, Spies has significantly commented that our knowledge of the avitaminoses has been substantially advanced by such observations and by testing out the newer pharmaceutical vitamins and ordering better foods.

There is also considerable difference of opinion as to just how much over or under nutrition exists in our country, in different states and among different classes of people. Chapter XXII (Stiebeling) will discuss that issue based on her extensive observations and studies in association with the United States Department of Agriculture.¹³ I think undernutrition produces more physiologic disturbances, but overnutrition (fat) may hasten the development of more pathologic change.

Living in a rich agricultural state, I do not see very many people needlessly undernourished. By proper planning and marketing and with attention to the methods discussed in chapter XVI (Cowgill) most of the borderline or marginal degrees of undernutrition which we uncover are economically unnecessary and stem from social maladjustment, anxiety states and outmoded medical advice. Undernutrition reduces vitality and well-being much more than it hastens decline or senility. It is hard to believe that "optimum nutrition" could endanger anybody's vascular system. The trouble lies in finding an "optimum diet"—because it varies with every locale, every people, employment and individual purpose, and nature has distributed around the world the widest assortment of adequate food sources. Some may like a "short life and a merry one"—at least at middle age that is their choice. Whatever the process by which it is brought about, 70 per cent of our Duluth Clinic¹⁴ patients are dying of cancer and cardiovascular-renal disease (including cerebral hemorrhage). This figure for cancer (18 per cent) is higher than the Minnesota State Board of Health figures (14 per cent) for 1941 and represents a higher than average of older people in our clientele. The approximate 50 per cent of cardiovascular renal disease¹⁵ is the same as Simms's claim for all deaths over age 10. I have checked these figures from four old line life insurance companies, and I present in table 2 the results from one of them. The others are almost identical. This detail of end results tells little, of course, relative to incapacity and sickness among the group I am discussing. From many studies dealing with the prognosis in degenerative heart disease it would be fair to state that there is an average illness (partial or complete) of about two years. fecting faculties of protein in their experiments with dogs poisoned by chloroform. Whipple's¹⁸ thesis that animal protein buffers the liver for blood plasma restoration is being augmented each month by various reports, all supporting the conclusions that protein safeguards the normal liver,¹⁹ even as dextrose (Mann and Bollman)²⁰ tides over the damaged liver. Philip Brown²¹ advises a high protein diet in ulcerative colitis in order to protect the liver. The papers by Patek²² and Butt and Snell²³ show the trend. Starvation edema is a matter of inadequate protein and liver efficiency. Space permitting, I could illustrate some of the follies of "arthritis," "colitis" and nondescript diets that decried the use of meat. A neglected and abused liver sets the individual toward a toppling over of his homeostasis. We may put down then, as our first duty to the aging, Teach them the importance of protein and how to get their quota, no matter how old they are, 1 Gm. per kilogram of body weight. The pellagrin and the alcoholic addict with tremens prove how dependent the brain²⁴ is on the liver.

Unfortunately, animal protein is expensive. Preservation and refrigeration add further costs. (Consult chapter XV, Kohlman.) Those purveying food are in full accord with the present nutritional program.²⁵ Utilizing the cheaper cuts of meat and making them palatable is a task for properly advised cooks, taught to develop an American goulash, but with a seasoning suitable to the American palate and without too much fat. (Consult chapter XVI, Cowgill.) We may, if harder put, learn to appreciate soy beans. It is a matter of education. It is distinctly possible to be a well fed vegetarian if milk, butter and eggs and cheese are plentiful and time is no object. Primitive peoples of our own times could teach us how the better to utilize the vitamin rich viscera. The occasional azotemic patient and the gouty, at some stage in their imbalance, should have a low protein intake, nearly every other indication, so much a part of books on diet, is a relic of a period in which attention was paid to the appearance and consistency of food and very little to its mineral, vitamin and chemical content.

2. *Fat* (consult chapter III, Bloor).—This is the food with which excess may well be dangerous, but leaving out what is needed is fatal. Burr²⁶ has demonstrated the essentialness of certain fatty acids particularly in terms of growth, milk production in cattle and vitamin B economy. Hansen, working with him, has been able to clear up some very trying instances of eczema and dermatitis in children through feeding of certain selected fatty acids. Fat improves the taste of everything. It is the good cook's delight. For the vigorous it invites

overindulgence, even if it does not "burn in the flame of the carbohydrate" both are very compatible (as the obese well know) and energy is released without the specific dynamic action loss characteristic of protein. Fat spurs all reserves, including vitamin B and protein. But when it isn't properly utilized, it clogs up the liver.

Biochemists and physiologists are baffled in attempts to trace fat through the human body and understand its interrelations with other food elements. In contrast, a lay knowledge which coined the phrase "living on the fat of the land" acclaims a great and popular appreciation of fat. The housewife chooses the beef where the muscle is well interlarded with white fat. Her husband chooses brown ties to match the gravy. For heavy work in low temperatures where much energy is expended, fat is the chief resource. Finnish woodsmen in northern Minnesota have shown me how they choose the fattest of salt pork, with amazingly sharp knives they sliced this off and sandwiched slabs of it between the bisceted halves of firm, hard loaves of bread. As they took a bite through this sandwich, I was told that some with inadequate teeth used the same sharp knife to sweep the mouth free from the segment without displacing a single whisker! With copious draughts of well sweetened coffee and condensed milk these men²⁷ could work prodigiously in subzero weather, feel comfortable and maintain their weight. "How about venison?" I asked. They looked very sad and replied "No good." "Eat big hunks, just like lay." Nature herself augmenting the efforts of the game warden!

The results of Lerry's rabbit experiments, in which he fed large amounts of cholesterol, have not been entirely refuted. He did prove that in the rabbit it seeped through the intima. Interest centers in the background of what cholesterol phagocytosed into the subintimal layers of the coronaries may later do in encouraging coronary inadequacy, sclerosis and thrombotic pluggage. Hurst²⁸, who has given much study to the subject of cholesterol (myxedema and related states), offers no especial support to Lerry's theory. From Isidore Snapper²⁹ comes a lively observation apropos of his recent experience in Japanese invaded China. He agrees with many other Occidental exchange professors who have reported from the Orient that the incidence of hypertensive disease and coronary complications is much less there than with us and implies that we have too much butter and cream at our plates. Snapper made a significant and naive observation to the effect that the very polite Chinese imparted to him the news that we Occidentals exude an unmistakable bovine aroma. Lest this be taken as a facetious implication, a recent report by Crohn and Drosd,³⁰ dealing with the mechanism whereby garlic taints the breath, showed that it is a matter of absorption and reaches the blood stream via the liver and thence to the lungs. Perhaps certain systems are surfeited with fat, and strawberry gallbladder and stones may not be the greatest insult resulting.

Recently, at a huge clinical panel discussion, the question was put to Himsley Harrison "If you had a patient with a family history of coronary disease, especially with thrombosis, would you advise the limitation of fat in the diet?" He answered affirmatively. I agree with him. Patients with gout (attacks precipitated by rich fatty foods) are very liable to coronary sclerosis. Such clinical evidence should not be undervalued, at least until more is known about fat metabolism. It is my opinion that, if 10 per cent of the necessary calories for the inactive elderly person are derived from fat, the bodily needs will be safeguarded. Some criticism of the higher calorie intake now advised for our recruits and practiced by our athletes is heard. There is the immediate effect (weight and mobility of recruits) and the remote effect (habits of eating during forced exercise) incompatible with later sedentary lives.

3 *Carbohydrate, Vitamins and Minerals*—Under this heading I choose to say little about their obvious virtues. I have tried to weave into this discussion a pattern that implies the great advantage of keeping nature's nutritional formulas intact, by avoiding overrefinement or processing, by getting a balanced ration and all the bodily needs will be contained therein. Age imposes certain deprivations—appetite, digestion, absorption—so that, even when a reasonable diet is consumed, certain deficiencies result. This may well occur even when obesity is present. The mouth (including the tongue, lips and fauces) has become the nutritional barometer. Ivy³⁰ states that gastric acidity slows up after 20, achlorhydria increases considerably after 40, by 65, 35 per cent of people do not secrete acid³¹ after a meal and 28 per cent show no response to histamine. Those losing their teeth (often without good reason, focal infection) frequently go through a period of adjustment to dentures when appetite slumps and subnutrition ensues. Lower plates are rarely secure. Sturdy square jawed people accommodate well to dentures, whereas neurotic and anxious individuals with natively poor bites or narrow receding mandibles find themselves unhappy. The former, with dental plates, say "These store teeth are better than my own." The latter try one dentist and denture after another. The prophylaxis for their dilemma goes back two to five decades. Is diet at fault? Weston Price³² thinks so. All nutritionists should read his book. He has gathered information from all around the world. The illustrations alone would seem to prove his thesis: native peoples (on the most varied source foods), when they get a balanced food and avoid overrefinement of flours and sugar excesses, bear children with properly formed jaws, the teeth are regularly spaced and both gums and teeth survive. On the contrary, as soon as they move to a region where overrefined carbohydrate in excess is available they promptly lose their teeth. The story is the same whether it concerns the cloistered group in the upper valleys of the Swiss Alps, the Hebrides Islands, African jungle tribes or our Eskimos and Indians. On the other hand, this thesis has so far little support from our leading dental colleges. Irwin³³ has collected a questionnaire from eight teachers holding professorships in basic university departments of medi-

cine and dentistry in the United States. Five questions were posed bearing on caries and pyorrhea alveolaris, resistance thereto, the effect of diets on pregnant women, the babies' teeth, dentition and general development. Opinion or belief that diet was of little import shined into the belief expressed by a few that nutrition was the basis of all caries and pyorrhea. I believe that this is one of the most pressing nutritional problems before us today. The lack of unanimity I mention is little short of alarming. The dental and medical professions have drifted too far apart. Harvard University's plan to remerge them is opportune.

Twenty per cent of the first draft³⁴ recruits could not qualify because of inadequate teeth. Surely something is wrong, and the best lead we have involves diets. Bleeding gums are controlled in most people by adequate citrus fruits, so-called trench mouth is an avitaminosis when tissue dies the Vincent's organisms multiply. The deeper deprivations that come from faulty absorption from the gastrointestinal tract or from diarrheas are pathologic. At the same time we do not know to what extent the age factor produces alterations of absorption and metabolism for which it isn't feasible to get all the essential vitamin and mineral even from a diet that is adequate. There is a good field here for vitamin reinforcement.

Vitamins have not been overemphasized, but the public (at least fifty million dollars' worth of vitamin preparations was sold in the United States last year) and doctors have taken the vitamin detour to supposed nutritional sufficiency and are using various vitamin compounds as they would "bitter tonics." THE JOURNAL (through the Council on Foods and Nutrition and the Council on Industrial Health³⁵) has given a clear statement of that fallacy, and it applies in part to the field of my discussion. Among segregated groups of the elderly there is a place for evaluating the benefit of certain selected vitamins, food enforcement with scientific controls. This has been reported on by Stephenson and his co-workers³⁶ in England. There was an advantage of such enforcement. I have found many situations and reported on a few in which such utilization in the old induced a health transformation.

Closely related to the tooth problem is that of calcium and phosphorus ratios in the body. Among the elderly (women more than men) senile osteoporosis frequently is found. Albright, Smith and Richardson³⁷ have linked this up with an endocrine (internal vitamin) estrogenic deficiency. Gardner and Black have reported less dense bone shadow (x-rays) in many nervous and underfed individuals with irritable colons. Hip fractures are common and often fatal, telescoping of the vertebra (with root pains and confusion with angina) occurs after insignificant trauma. By whatever method we try to recalcify such bones, the results are discouraging. I stress this to question the use of milk as a source of calcium for old people. They do not need the fat in whole milk, skim milk is constipating if

taken in large amounts and bulky foods promoting residues are left out. Cheese, buffered with vegetables, is more practical.

Water is too often neglected. Coffee and tea are preferable to chocolate, and aside from encouraging insomnia, few suffer from their abuse. When not too strong, even in advanced years, these help greatly to keep up fluid intake. They are too often left out on rather poor excuses.

OPERATIONS AFTER SIXTY-FIVE

Surgery for the elderly (cancer, gastrointestinal, genitourinary and central nervous system) is a test that many elderly must meet. Few prepare for it. Emergencies shorten the period of possible preparation. The medical attendant has a heavy responsibility which the surgeon should share with him. At the same time necessary surgery must not be withheld, because many of the elderly do astonishingly well even when the severest operations are done.

Wilcox and Clagett,³⁸ reporting from the general surgical sections of the Mayo Clinic for 1939 and 1940, listed 1,204 such patients over 65 operated on. The mortality was not high (8 per cent) for benign disease and operable cancer and 16 per cent for inoperable cancer and palliative operations. However, only 20 per cent (one in five) failed to have some significant postoperative complication. Naturally these were in the nature of cardiovascular insults (thrombophlebitis, embolism, pulmonary atelectasis and cerebral and kidney complications). This is what we all see within this group. What better preparation could they have had than even a fair nutritional balance? Added incentive to "keep your body as fit as you can as long as you can" arises from the great likelihood that some major operation or infection is in the offing. These operations are part of the price we shall pay for both the fuller and the longer life.

GENERAL SUMMARY OF DIETARY SUGGESTIONS FOR THE OLD

1 Elderly people should start the day with a good breakfast. It should include some substantial protein, and whatever else depends on body weight and activity. Protein adequacy must be maintained at all ages.

2 As effort lessens and sedentary life supervenes, weight rise or fall should dictate the proportion of carbohydrate taken, and as much of this as possible should be from whole grain. Whole bran is objectionable; cracked wheat products are not. Enriching flour may be a good expedient but the objection to dark breads should be lived down. Potato is the next best starch.

3 For the obese, vegetables and fruits should act as the "fillers" and provide appetite and zest for eating by meticulous preparation and serving.

4 The elderly should eat fat sparingly, even as the middle aged should use it cautiously. The high cholesterol sources (egg yolk, cream and animal fats) should probably be curtailed wherever body build, family history and other indications portend atherosclerosis. It is the one decisive indication for dietary restriction after full stature has been attained. The danger of high blood cholesterol is not universal.

5 Tea, coffee and alcohol are useful stimulants. The abuse of alcohol places it for some people in the category of both refined carbohydrate and animal source fat. As a vasodilator it inspires as well as flushes the aged.

One cannot say as much for tobacco. It soothes and cuts off circulation. The quiet postprandial puff is rapidly becoming a continuous process. Tobacco is safer after 60 than before, because age has by that time made the blood vessels less elastic and labile.

6 Food and water (hot drink) taken at regular intervals revive the old. Food becomes the best sleep producer even though early wakefulness follows. Fruit juices add the needed vitamin content.

7 Hunger lessens as age advances. Foods useless calorically (condiments, broth, relishes) have a place. The teeth, gastric acidity, probably absorptive powers, vitamin storage—all begin to fail with age. We are able to compensate for these losses with vitamins, iron, calcium hydrochloric acid and a balanced diet. The mouth becomes the nutritional barometer of health.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE

HOWARD A. CARTER, Secretary

MAICO HEARING AID, ACE MODEL, ACCEPTABLE

Manufacturer: The Maico Company, Inc., 2632 2636 Nicolet Avenue, Minneapolis

The Maico Hearing Aid, Ace Model, is a vacuum tube instrument. The dimensions and weights of the various parts are as follows:

Microphone and amplifier unit, oval shape, 2 1/4 by 1 1/4 by 1 inch, weight 2 1/2 ounces.

A and B batteries in leather case 4 1/2 by 4 by 1 inch, weight 13 1/2 ounces. Crystal receiver, 1 inch diameter by 3/16 inch thick.

BATTERIES

Maico Hearing Aid, Ace Model

The A battery is a 1.5 volt cell, Maico A No. 725. The current drain is 70 to 80 milliamperes. The B battery is an Eveready 45 volt unit and shows a current drain of 2.30 milliamperes. The two are assembled in a single unit by a well designed connection.

INTERNAL NOISE

With customer fitted ear mold the instrument can be turned to full volume without feedback squeal.

ACOUSTICAL GAIN

The following figures give the order of magnitude of the increase of sound intensity level at the ear of the wearer over that at the microphone under normal conditions of use as shown by audiometric measurements. They are not the same as the electrical amplifications shown by measurement of electrical input and output. Measurements were made only at octave intervals.

Frequency	125.756	512.248	4,096
Volume setting full on	Nil	24.43	10 decibels

ARTICULATION

The usual syllable and sentence lists were used with hard of hearing subjects at a distance of 5 feet in a quiet room, with instrument set for comfortable hearing. The articulation tests showed satisfactory results.

The Council voted to accept the Maico Hearing Aid, Ace Model, for inclusion in its list of accepted devices.

AUSTIN C SMITH M.D. Secretary

HUMAN CONVALESCENT MEASLES SERUM and HUMAN CONVALESCENT SCARLET FEVER SERUM

HUMAN CONVALESCENT MEASLES SERUM

Measles (morbilli) is an important public health problem because of its universal distribution, the susceptibility of both sexes, and because no age group appears to be exempt, although the majority of the attacks occur in children under 5 years of age. The disease is extremely infectious and may spread rapidly in unprotected communities, there appearing to be little evidence that natural immunity ever occurs¹. Although the acute manifestations may be extremely mild, the possibility of complications must always be considered, and it is now generally agreed that in many instances children especially, should be afforded some degree of protection. Other factors requiring special consideration are malnutrition, debilitating diseases and pregnancy. The control of measles from a public health point of view appears to have met with little success² and isolation of the sick has not been generally effective in protecting others from the disease³. At the present time there appear to be two agents which have shown some success in the prophylaxis and modification of an attack of measles: these are Immune Globulin (Human), which has been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies, and Human Convalescent Measles Serum.

The use of human convalescent measles serum dates back about twenty five years, and encouraging reports have appeared in many parts of the world. Harries⁴ reported that five doses of 10 cc of recently prepared convalescent serum given intramuscularly would protect an exposed child for a period of about three to four weeks. This investigator could obtain an attenuation of an attack of measles by using lesser amounts or delaying the injection for four to eight days after exposure. Attenuation did not appear to prevent the development of immunity against subsequent attacks. Again Harries claimed that the serum had no effect when injected after the eighth day following exposure, unless given intravenously. Price⁵ states that the intramuscular injection of human convalescent measles serum produces a passive immunity lasting about one month; if the injection is given after the sixth day the attack will persist but in a modified form which nevertheless results in a lasting active immunity. He suggests an average dose of 5 cc for a child, the dose being increased as needed and he believes that all children under three years of age exposed to measles should be given preventative therapy.

Grod⁶ studied the use of mixed serum in 170 children and reported the serum was tolerated even on repeated administration. Doses of 15 to 20 cc, usually injected on the fourth or fifth day of incubation, afforded apparently complete protection in 47.7 per cent of 44 children who were closely observed. In 36.3 per cent the severity of the attack appeared to be reduced, and in 16 per cent there was no perceptible effect. According to Grod, the results were about the same as those obtained with placental immune globulin, human, but the serum seemed to be better tolerated. A communication by Timmerman⁷ indicated that he obtained partial or complete protection in the majority of 98 Dutch children who were at home and in various

institutions. In discussion of the prophylactic work which the physician may undertake, de Ruiter⁸ recommends administration of the serum on the fourth or fifth day of incubation to obtain an attenuated attack. Hoyne⁹ discussed the use of convalescent serum, and while emphasizing the value of the prevention in hospitals and other institutions, suggested that intramuscular injection of 5 to 10 cc within three days of the date of exposure would result in protection for three weeks. If an attenuated form of the disease is desired, serum or immune globulin may be employed later in the incubation period, although a warning was issued against employing this procedure in a hospital since the modified disease may still be contagious and susceptible individuals may develop severe attacks. This article also discusses the use of 10 to 30 cc of serums on patients in the preeruptive stage by Gunn in 1934, the intravenous injection of 5 cc in children by Kohn, Klein and Schwartz in 1938 with alleviation of the disease in about 85 per cent of the cases, and the work of Connor reported in 1939, giving a total of 50 treated cases. The text of Hoyne's paper was substantiated in the accompanying discussion by one clinician who had used convalescent serum in a number of cases with beneficial results.

In reporting on the use of serum in an outbreak of measles in Wellington in 1938 Champaloup⁸ claimed he has been able to prevent or attenuate the attacks in exposed children and to decrease the time for recovery and the complications. Bull⁹ used adult pooled serum in an outbreak of measles in Melbourne, and his observations were in agreement with those of Champaloup in that the severity of the attacks appeared to be lessened and the evidence of complications decreased. Champaloup began his injections with a minimum of 5 cc but later increased this to a minimum of 7 cc, Bull used 10 to 20 cc according to the age and condition of the patient. Thalheimer¹⁰, Lempriere¹¹ and Loewenberg¹² also have issued favorable reports.

While the evidence on the use of human convalescent measles serum in the treatment of the full blown disease is not impressive, the results from its use for prophylaxis or early modification of measles are favorable in many cases and they appear to be about equal to those resulting from the use of Immune Globulin (Placental Extract). The Council on Pharmacy and Chemistry has declared this serum acceptable for inclusion in New and Nonofficial Remedies and several brands are now described in N N R 1942.

HUMAN CONVALESCENT SCARLET FEVER SERUM

Like measles scarlet fever (scarlatina) is a disease which is highly infectious and no age group appears to be exempt, although the majority of the attacks occur in the young. Agents for prophylaxis and modification of the course of the disease are scarlet fever streptococcus toxin, scarlet fever streptococcus antitoxin and human convalescent scarlet fever serum. The use of serum for prophylaxis and treatment has been discussed by Hoyne, Levinson and Thalheimer (1935), Hyland and Anderson (1937) and Moore and Thalheimer (1939). The latter authors¹³ cited the work of the aforementioned and various other investigators when reporting on the bactericidal substances and antitoxin found in the serum of patients convalescing from scarlet fever. These authors advise pooled specimens for a polyvalent serum. A later communication by Thalheimer¹⁰ discussed dosage and use of serum intravenously as well as intramuscularly, the former route being recommended for the treatment of the disease. have also commented on the value of pooled convalescent serum. Viole¹⁵ claims that any reactions are easily controlled.

Thalhimer,¹⁶ Fox and Hardgrove¹⁷ and Rascoff and Nussbaum¹⁸ have made some comparison between sulfamidamide and human convalescent scarlet fever serum. Thalhimer advises that statistical evidence on the concurrent use of sulfamidamide is lacking, whereas Rascoff and Nussbaum suggest its concurrent use in severe and moderately severe scarlet fever until evidence to the contrary is produced.

Lucchesi and Stein¹⁸ compared the effect of four types of treatment on fever and complications in 1780 patients: one group was treated symptomatically, another received scarlet fever antitoxin, another group was given foreign protein in the form of diphtheria antitoxin and the fourth group received convalescent serum. The authors concluded that convalescent serum in the doses used (30 to 90 cc.) had no effect on the reduction of the febrile state or of complications. Like Lucchesi and Stein, Toomey²¹ is not enthusiastic over the results which follow the use of convalescent serum. However, Schultz practices passive prophylaxis in his clinic chiefly with human serum, and Bejarano²¹ after studying the use of serum in soldiers, concludes that it is of value in the prevention and treatment of scarlet fever.

The Council has recognized the use of this serum for prophylaxis but since opinion was somewhat divided on its merit in the treatment of scarlet fever inquiries were addressed to professors of pediatrics and recognized investigators in the field of serum therapy in an effort to obtain a representative judgment. The replies of the authorities consulted are quoted in part.

Dr. Francis G. Blake, New Haven, Conn.: "Ever since 1924 we have found the horse scarlet fever antitoxin so satisfactory, provided adequate dosages are used, we have not had any real experience with human convalescent serum. While it is true that an occasional patient highly sensitive to horse serum has been treated with human serum, the number is too small to be of any statistical significance. In my opinion the major if not the sole value of human serum depends on its antitoxin content. This is of course relatively low compared with horse antitoxin. In severe cases I think it would require anywhere from 300 to 500 cc. of human serum to get the same effect expected from 20,000 to 40,000 units of antitoxin which is the general range of dosage that we use in patients sick enough to be treated. The criteria for benefit are first rapid fading of the rash, second critical fall of temperature and pulse rate, provided the case is not too far advanced and complicated by sepsis. It is my opinion that the septic aspects of scarlet fever are perhaps now better treated by chemotherapy than by so-called convalescent immunotransfusion."

Dr. Murray B. Gordon, Brooklyn: "In answer to your recent letter with reference to the use of convalescent serum in scarlet fever, I wish to advise you that I do not use it in my private practice or at the Kingston Avenue Hospital. I am enclosing a reprint of some recent work done at the hospital with scarlet fever antitoxin (Gordon, Murray B., Litvak, Abraham M. and Caronna, Victor: Streptococcal Meningitis and Abscess of the Brain Complicating Scarlet Fever, *Am J Dis Child* 53: 1447 [June] 1937)."

Dr. Archibald Hoyne, Chicago: "For approximately twenty years we have used human convalescent scarlet fever serum for the treatment of scarlet fever at both Cook County Contagious Disease and at Municipal Contagious Disease hospitals. Originally it was given only to a comparatively few patients who

were suffering from severe types of the infection. After the serum center at Michael Reese Hospital was established, the supply of convalescent scarlet fever serum was made available in much greater quantity and its use was extended to an increased number of patients. Since 1931, when the Samuel Deutsch Serum Center was founded, more than 23,025 patients with scarlet fever have been treated at Municipal Contagious Disease Hospital. Approximately one third of that number received scarlet fever convalescent serum, which was administered as a rule only to patients with the most severe types of the disease. Our reasons for believing that this form of therapy is of value are based on the following:

The customary sharp decline in temperature within twelve hours after the administration of serum.

The voluntary statement of patients with regard to their improved well being the day after serum administration.

The marked improvement in throat symptoms, the rapid fading of the rash and the small number of complications in serum treated patients.

We also give convalescent scarlet fever serum late in the course of scarlet fever regardless of the duration of the disease if the patient has serious complications or is in a critical condition. Moreover, our fatality rates are usually extremely low for hospital patients.

In my opinion there is little if any difference between the therapeutic results attained with human convalescent scarlet fever serum and scarlet fever antitoxin in the early acute stages of scarlet fever. I feel convinced this is true notwithstanding that convalescent serum may possess far less scarlet fever antitoxin than scarlet fever antitoxin serum.

For your convenience I am herewith a reprint relating to this subject which you may care to glance through (Hoyne, Archibald I., Foxman, Sidney O. and Thalhimer, William: Convalescent Scarlet Fever Serum, *THE JOUR. A., Sept. 7, 1935*, p. 783).

Dr. P. I. Lucchesi, Philadelphia: "In 1933 we studied a series of 1780 scarlet fever patients with various types of treatment including convalescent serum and concluded that it is neither practical nor of value in the treatment of scarlet fever."

I am enclosing a reprint in which the exact number of cases treated by various methods is given (Lucchesi, Pascal F., and Stein, Bernard B.: A Comparison of Therapeutic Agents in the Treatment of Scarlet Fever, *Pennsylvania M J* 43: 162 [Nov.] 1940). I am of the opinion that scarlet fever antitoxin is of greater value for the treatment of this disease than convalescent serum since most of the symptoms and signs in the early stages are due to the absorption of the scarlet fever streptococcal toxin.

In my experience I have found convalescent serum in the treatment both therapeutically and prophylactically helpful in only one disease—that is, measles.

Dr. Edwin H. Place, Boston: "I can say with complete definiteness that convalescent scarlet fever serum has a striking effect on the toxemia of the disease practically without exception. The effects produced are the relief of fever, central nervous system effects when present, and disappearance of the exanthem and emanthem. In about 50 per cent of the cases there is relief of the more obvious bacterial damages and, although this may be due to antibacterial bodies, I am strongly inclined to believe this is a secondary effect from neutralization of the toxin. These opinions are based on several thousand cases with concomitant controls over the past twenty years."

We have not been able to find any better results from scarlatinal (horse) antitoxin. For several years we have used almost wholly the convalescent serum instead of horse serum antitoxin, as the antitoxin has been associated with frequent and at times severe serum disease. The state laboratory has not yet been able to produce a serum as free from after effects as that for diphtheria. The Lederle serum, and from Toomey's results, Parke Davis serum are extremely satisfactory but no better than the convalescent serum.

Dr. John Toomey, Cleveland: "Human scarlet fever convalescent serum has a place in the treatment of toxic individuals who are allergic."

Treatment involves a consideration of many factors, the first of which is who should be treated by specific therapy, either human or animal. The mortality rate from scarlet fever is extremely low (almost negligible), and the majority (nearly

90 per cent) of those who die do so not from toxicity but from sepsis, long after plenty of antitoxin has been formed in the blood stream. Therefore it would seem that specific therapy of any kind should be used only where clinically there is a marked amount of toxicity, and only at the start of the disease.

"When antitoxin was first brought out by the Dicks, we used some of the first lot of antitoxin they made but stopped after treating 14 cases. We lost 3 patients after intravenous injections of this material with protein shock ending in pulmonary edema, the symptoms starting about twenty minutes after the antitoxin was given. We refused to use antitoxin further and from 1925 to 1931 used convalescent scarlet fever serum in hundreds, in fact a few thousand cases—the exact number I haven't at hand. However, we know that the temperature does drop when a pooled yield of human serum is used and, it is my impression, although I haven't proved this, that the complications were lessened.

"Several years ago the old scarlet fever antitoxin was concentrated and, instead of using 20 cc. as was once the dose, one could use the newer material concentrated from 20 cc. to 3 cc., the albumin fraction having been removed (Lederle and Parke, Davis & Co.). We had so few reactions and the response was so uniform that we saw no further need to use human convalescent serum in the majority of instances because we now had a standard product which could be checked and which did not vary. The results are on record, and they are excellent. Since we have reported these, we have used it (Lederle Laboratories, Inc., and Parke, Davis & Co.) in over a thousand more cases and have no reason to change our mind, in fact, we feel that the complication rate has definitely decreased. This latter is difficult to estimate, however, because as you know we have the added factor of sulfonamide therapy to consider. In 1936 and 1937 we had 13 cases of streptococcal meningitis with one recovery, and in 1938 and 1939 12 cases, all of which recovered. Thus the effects of the dye on complications has to be remembered in the general picture.

"It is our impression, however, that there has been a definite decrease in complications with the use of specific serums where sulfonamides have been used. Our practice is to use sulfonamides late, not early, because we have found them to be of no value in toxic conditions.

"It is my opinion that human convalescent serum does have a place in treatment of allergic types of individuals, although I will admit that the existence of these cases is more apparent than real. We have not found it necessary to use human convalescent serum except in 2 instances in the past two years."

Dr. Franklin Top, Detroit: "I am enclosing two reprints which serve to summarize the experience of this service with respect to treatment of moderately severe scarlet fever, not only with convalescent serum, but comparing its use with scarlet fever antitoxin and a control serum consisting of 1,000 units of diphtheria antitoxin. In a subsequent study reported in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, convalescent serum was compared with scarlet fever antitoxin and sulfanilamide in alternating cases of moderately severe scarlet fever. Definite criteria of evaluation were set up for both studies, and the results are given in the papers. (The reprints sent are Top, F. H., and Young, D. C. Specific and Non-specific Serum Treatment of Scarlet Fever, *Am J Pub Health* 29:443 [May] 1939; Top, F. H., and Watson, E. H. Reduction of Serum Reactions, *Am J Dis Child* 62:548 [Sept.] 1941; Top, F. H., and Young, D. C. The Treatment of Moderately Severe Scarlet Fever, *THE JOURNAL*, Dec. 13, 1941, p. 2056.)

"Briefly, 30 cc. of convalescent serum given intramuscularly appears to be as good as a therapeutic dose (6,000 units) of scarlet fever antitoxin, and both appear to be slightly better than sulfanilamide given by mouth in a dose approximating roughly $\frac{3}{4}$ to 1 grain per pound of body weight daily for an average of six and a half days during the acute stage.

"In the first study it was apparent that the use of a non-specific (1,000 units of diphtheria antitoxin) made a marked difference, and the effects, with respect to the number and proportion of cases which needed augmented treatment, on the temperature pattern, number of complications and dismissal status are noted.

"We have also used convalescent serum by the intravenous route in doses of 30 to 100 cc. in borderline septic cases and in some instances of moderately severe scarlet fever. Used by this route, effects are often dramatic, as much so as the use of scarlet fever antitoxin intravenously in cases of toxic scarlet fever.

"I believe that convalescent serum, when available, is of distinct value because therapeutic effects are obtained without sensitizing a person to horse serum which follows the use of the scarlet fever antitoxin. I realize that during the past several years antitoxins have been despoiled to such an extent that serum reactions are much less frequent, but serum sensitization still occurs. When available, therefore, I prefer to use scarlet fever convalescent serum for the moderate or moderately severe case. It is wholly inadequate in the treatment of the septic or toxic types."

Dr. Bernard B. Stein, Philadelphia: "In my experience of eight years as chief resident physician of Philadelphia Hospital for Contagious Diseases, where I saw and treated upward of 100,000 cases of scarlet fever, I believe the pooled scarlet fever convalescent serum has a definite place in treatment—in the patient who is very septic or toxic and is extremely allergic to antitoxin (horse serum)."

Dr. Conrad Wesselhoef, Boston: "The efficacy of human convalescent scarlet fever serum in the early treatment of scarlet fever was established prior to the introduction of the Dick antitoxin. I have in mind a composite chart to that effect shown at several meetings by Dr. Edwin H. Place of the Boston City Hospital. Since the introduction of the Dick antitoxin, and even since its great improvement whereby serum sickness has been greatly reduced, pooled convalescent serum has a distinct place in the therapy of scarlet fever.

"From a purely theoretical point of view, the attitude that because convalescent serum is not standardized it is always inferior to standardized antitoxin is not in keeping with the limitations of our present knowledge of the disease. Furthermore, it is obvious that a commercial antitoxin, which must be polyvalent to meet the possible needs of different strains, may be lacking in a certain direction quite as much as an unstandardized pooled serum. The advantage of human serum as a means of avoiding serum sickness has been reduced by the refinement of antitoxin, but such refinement has not as yet overcome this advantage.

"Time does not permit me to produce exact figures. Roughly, my experience in scarlet fever covers 20,000 cases at the Haynes Memorial Hospital. The number treated with convalescent serum was increasing up to the introduction of the Dick antitoxin. As the first Dick antitoxin results gave 35 per cent serum sickness, the convalescent serum was again preferred. Three bad Arthus reactions caused us to give up antitoxin entirely. Then as the antitoxin was improved it again came into favor. It would take too much time from my secretarial staff to give you the number of cases in which convalescent serum has been used, but I continue to use it in about one fifth of the cases. As we have had an average of 100 cases of scarlet fever on the daily census for the past six months, it would seem that over this period 120 cases have been given convalescent serum.

"The criteria of benefit are the abrupt drop in the fever and the blanching of the rash. In the past ten years I have rarely lacked such cases to show at clinics. The dramatic results are so well known when the serum is given early and in adequate dosage that I am not inclined to yield my preference for convalescent serum. Such preference is not by any means absolute, as there are situations in which I prefer antitoxin."

In view of the evidence available, the Council recognized this serum as being of value in transferring passive immunity to a patient exposed to scarlet fever. Existing evidence does not appear to indicate that it is wholly adequate in the treatment of septic or toxic types of scarlet fever, but the consensus seems to be that this serum may have a place in the treatment of individuals sensitive to horse serum and where it is desired not to sensitize a person to horse serum. The Council on Pharmacy and Chemistry has declared this serum acceptable for inclusion in New and Nonofficial Remedies, and several brands are now described in N. N. R. 1942.

INSULIN RESISTANCE

Many cases in which insulin has failed to lower the blood sugar in the normal manner have been recorded since insulin first came into use in 1922. Glassberg, Somogyi and Taussig¹ observed a diabetic patient who was relatively refractive to insulin for some months and who responded only to enormous doses, as much as 1,100 units in twenty-four hours. The diabetes in this case was due, the authors suggest, not only to a lack of pancreatic secretion but also to a lack of some substance which activates insulin, probably a muscle enzyme (phosphatase, insulin complement, glycomulin). Apparently there may exist two types of diabetes: one due to pancreatic disease, which responds to insulin, the other due to a deficiency in the production of a substance which activates insulin. Marble² reported observations on a woman with chronic rheumatoid arthritis and diabetes whose insulin requirement varied from 240 to 675 units daily. Evidence failed to indicate that a pituitary, adrenal, thyroid or gonadal influence was in any way responsible for the resistance. Wiener's³ patient was rescued from coma by large doses of insulin. He had received as much as 3,250 units in twenty-four hours, probably the largest amount ever administered to a human being. The patient required large doses during the subsequent course of observation (five months). Glen and Eaton's⁴ patient was given from 900 to 1,059 units daily for a period of twenty-seven days without appreciable effect on the blood sugar or glycosuria. Martin and his co-workers⁵ treated a diabetic patient whose insulin resistance was apparently precipitated by hypersensitivity to protamine zinc insulin. He had received 6,375 units of insulin in eleven days, with

1,205 units as the highest dose in twenty-four hours. These authors, who collected 26 cases of insulin resistance from the literature up to 1941, call attention to the frequency with which allergy has been recorded in association with this condition. In the case reported by Regan, Westra and Wilder⁶ a definite cause for resistance was not found. Administration of dihydroxyestrone was without effect. Glass and his associates⁷ gave 85,000 units of insulin to a patient in a five and one-half month period. During episodes of ketotic acidosis it was necessary to give 2,360, 2,500 and 2,795 units of insulin in twenty-four hours before adequate control was accomplished. A definite cause for the insulin refractory state could not be determined. Therapeutic procedures included roentgen irradiation over the pituitary and the administration of hypocaine. However, it was not possible to establish a definite relation between these forms of therapy and the improvement which followed their use. The excessive need for insulin subsided six months after its onset and the patient remained mildly diabetic for the subsequent six months. Wayburn and Beckh's⁸ patient was given from 500 to 2,400 units of insulin daily for four months. Although the patient was highly resistant to insulin he nevertheless utilized insulin to some degree. A substance capable of elevating the blood sugar levels of rabbits was repeatedly demonstrated in the patient's blood. The authors assume the presence in the blood of this patient of an insulin antagonist substance.

Factors known to cause insulin resistance include acidosis, infections, sepsis, overactivity of physiologic antagonists of the pancreas, namely the pituitary, the thyroid and the adrenal glands, and liver diseases, in particular hemochromatosis. From the amount of insulin required to keep a depancreatized dog fed on ordinary diet Root calculated that a man of average weight would require 200 to 300 units of insulin daily. Patients who require more insulin than this amount probably lack some factor other than insulin. The conception of insulin inadequacy as the cause of hyperglycemia, glycosuria and ketonuria has received much support from the success of insulin therapy. Although insulin has made it possible to restore diabetic patients to a normal state of carbohydrate metabolism, this substance may be only one of several factors in the complicated mechanism of the regulation of the carbohydrate metabolism. More recent researches, in particular those of Housley and his co-workers, have established the role of the so-called diabetogenic factors of pituitary origin resulting in a disturbance of the normal regulation of carbohydrate metabolism.

The anterior pituitary and the pancreas apparently act antagonistically in the control of the carbohydrate metabolism

Wesselow⁹ showed that the blood plasma of some elderly obese glycosuric patients, when injected into rabbits, would diminish the hypoglycemic action of insulin in a manner closely resembling that observed by other workers with extracts of the anterior pituitary gland. The plasma of young diabetic patients and of normal control subjects gave entirely negative results. This result suggests that the blood contains a substance with a diabetogenic action in certain cases of diabetes. Apparently lack of insulin is not always responsible for the disturbances of carbohydrate metabolism of the diabetic. Himsworth¹⁰ has established, on the basis of his dextrose-insulin test, the existence of two types of diabetes mellitus, one in which the patient is insulin sensitive, apparently for lack of insulin, the other in which the patient is insulin insensitive for lack of an unknown factor which sensitizes the body to insulin. These patients are abnormal in being unable to react to an increase in dietary carbohydrates by an increase in their insulin sensitivity as the result of a lack of some unknown factor which in the normal subject produces sensitivity to insulin. In the case reported by Glen and Eaton, insulin tended to decrease sugar tolerance. Injection of the patient's serum into rabbits diminished their response to insulin and induced a degree of insulin antagonism. They therefore prefer the term "insulin antagonist" with reference to their case. The favorable effect of dihydroxyestrin was probably due to the antagonistic effect of this hormone on the anterior lobe of the pituitary, which then counteracted the production of the insulin antagonistic substance. It was logical to assume that the patient's blood contained a specific insulin antagonistic substance.

Insulin resistance and insulin antagonism are thus only one aspect of the complex problem of carbohydrate metabolism, involving as it does the liver with its glycogenic and glycolytic functions, and the synergistic and antagonistic effects of the various endocrine glands.

THIAMINE REQUIREMENT OF MAN

Several investigators have shown that the extent of urinary excretion of thiamine is an index of its status in the nutrition. In thiamine clearance studies in man Melnick and Field¹ demonstrated that all the subjects in their normal group, but none in the deficient group, excreted in excess of 50 micrograms of total thiamine during the four hour period following parenteral administration of 540 micrograms of thiamine.

Objective thiamine balance studies were made by Melnick² in man to detect the requirements for thiamine and the incidence of inadequate intake among apparently normal subjects. A study on 39 male and 33 female persons subsisting on adequate diets indicated good correlation between the urinary excretion of thiamine and the adequacy of the dietary level prior to conduction of tests. The normal person who consumes an adequate diet apparently tends to excrete part of the extra dietary thiamine in the urine. The deficient subject tends to conserve dietary thiamine to replenish depleted stores in the tissues and does not waste it by urinary excretion. When a test dose of thiamine was superimposed on the dietary intake, the extra vitamin was utilized like that obtained from the diet, it was conserved or wasted depending on the nutritional status of the subject.

This tendency of the depleted subject to conserve thiamine was observed in both the clinical and the experimental deficiency of thiamine. Thus the addition of thiamine to the inadequate diet to raise the level of intake to that of the normal group does not effect a parallel increase in the urinary thiamine excretion for a considerable period of time. Prompt response of normal subjects to variations in thiamine intake occurred while they were subsisting on their usual diets, which furnished approximately 1 mg of thiamine daily. Apparently a constant daily intake of 1 mg is sufficient to saturate the subject to such an extent that there is no necessity to conserve extra dietary thiamine. The recommended daily intake of thiamine is approximately 500 micrograms per thousand calories.

In a collateral study on 116 persons at the University Hospital, Ann Arbor, and at the Food Research Laboratories, Melnick showed that only 73 per cent of those apparently normal excreted in the normal range. The persons studied included mainly staff members of the hospital or laboratory personnel, whose diets were not restricted.

This high incidence of failures among so-called normal subjects to pass all the clearance tests, Melnick believes, is explained by the observations of Lane, Johnson and Williams at Summit, N. J., that the average American diet prior to the advent of enriched bread and flour furnished only 320 micrograms of thiamine per thousand calories. The observations of Melnick suggest that thiamine subnutrition is probably common even among persons who subsist on what is considered a normal diet. The correction, as was pointed out by Cowgill³ as early as 1938, lies principally in improved diet. The problem calls for particular attention by the practicing clinician and students of preventive medicine, public health and nutrition.

Current Comment

STRUCTURE OF BIOTIN

Success seems to have crowned the attempts of du Vigneaud of Cornell University Medical College and his collaborators to determine the exact chemical nature of biotin. The structural formula of this substance has now been published¹. The compound is bicyclic and possesses a five membered urea ring, a ring containing sulfur in thio-ether linkage, and a fatty acid side chain. This chemical agent exerts a biologic effect in extremely great dilution and may be classed as one of the most active substances known. The growth promoting effect of biotin on an appropriate strain of yeast is noticeable when the factor is present in a concentration of only 1 part in 400 billion². This may be compared with the dilating effect of epinephrine on the pupil of the frog eye, which can be demonstrated in a concentration of 1 in 20 million, and with the effect of thyroxin on the metamorphosis of the tadpole which is demonstrable in a dilution of 1 to 5 billion³. This great potency alone makes biotin of unusual interest. However the substance is also involved in animal metabolism and is recognized as a member of the vitamin B complex. Although human beings apparently require biotin,³ this phase of the biotin problem has been relatively little studied and requires further investigation. Kogl and Tonnies, who first isolated biotin, obtained only about a milligram of the crystalline material from a fourth of a ton of dried egg yolks. While better methods of obtaining it from natural sources are now available the substance is still difficult to prepare and is most costly. A more plentiful supply of biotin would facilitate further study and would undoubtedly lead to a fuller understanding of its function. The elucidation of the chemical makeup of biotin is an initial step in the direction of making the vitamin more readily available through synthesis.

MICROCEPHALY AFTER PELVIC IRRADIATION DURING PREGNANCY

The possibility that exposure of the human ovary before conception or of the fetus in utero to radium or roentgen irradiation might be injurious has long been a matter of concern. Three types of exposure are recognized: therapeutic roentgen and radium irradiation of the ovaries prior to conception, diagnostic roentgen exposure of the fetus in utero and therapeutic roentgen and radium exposure of the fetus in utero. The therapeutic irradiation may be without effect on ovulation or it may cause temporary or permanent sterility. Evidence does not indicate, however, that such treatment has a deleterious effect on the health or development of infants if there is subsequent conception. During pregnancy the chief use for diagnostic roentgen irradiation lies in the field of pelvic mensuration. Thousands of such exposures have been made and evidence indicates that such irradiation is not detrimental to the infant. Finally, therapeutic amounts of radium and roentgen exposure are

likely to be employed early in the life of the embryo, usually for the purpose of producing abortion. Such exposures have been followed by the birth of both normal and malformed offspring. Now Murphy and his colleagues¹ report a case in which embryonic irradiation was intentionally performed for the purpose of interrupting pregnancy. Previous to this occasion the mother had given birth to four bright, normally developed children. Irradiation did not produce abortion and the infant subsequently born, apparently at term and after normal labor, was microcephalic and at 14½ months was generally underdeveloped with an average mental age of 54 months. These workers point out that when pregnancy is not terminated in consequence of irradiation the physician or roentgenologist should insist that it be actually terminated—if not by the roentgen exposure then by some infallible means. From this study and the information previously available it is concluded that the human fetus should not receive large amounts of radium or roentgen irradiation. If fetal death or abortion does not follow such exposure immediately the pregnancy should be terminated at the earliest suitable moment.

THERAPEUTIC USE OF RADIOACTIVE SUBSTANCES

As pointed out by Low-Beer, Lawrence and Stone¹ in a study of the therapeutic effect of radiophosphorus, radiostrontium and radioiodine the problem of evaluation becomes difficult when one is dealing with chronic leukemia, since in this condition there is such great variation in length of life regardless of treatment. The distribution and metabolism of radioactive phosphorus in animal and human tissues indicate they point out, that it should prove to be valuable as a therapeutic agent for some diseases, particularly chronic leukemia and polycythemia vera. In reporting its use on a carefully observed group of patients seen between 1937 and 1941 they conclude that radioactive phosphorus in sodium acid phosphate has proved to be of great value in the treatment of chronic lymphatic and myelogenous leukemias, polycythemia vera and lymphosarcoma. Its use in the treatment of Hodgkin's disease is not yet established by experience. Its place in the treatment of multiple myeloma and other conditions is also not well established, although the inevitably fatal outcome of these diseases justifies its experimental trial. The use of other radioactive elements such as strontium, iodine, element 85 and phosphorus in chromium phosphate appears to be of some value in certain conditions. Radioactive strontium, for example, is selectively taken up by the bones and its role in the treatment of neoplastic disease of bone deserves to be and is being investigated. Likewise radioactive iodine 131 has proved effective in the treatment of hyperthyroidism but has not yet been tried on many patients. The further possibilities of using radioactive elements in various compounds which might localize in certain tissues, these investigators conclude, is unexplored territory with great potentialities.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

NEW PLANS FOR MEDICAL EDUCATION

Specialized Training Programs of the Army and Navy

The armed forces have need of the services of men with specialized training. They will utilize available facilities of certain American colleges to institute the training. Those receiving the training will be on active duty in uniform receiving pay and general military discipline. Arrangements will be made with various selected institutions for housing and messing facilities as well as for the actual training.

The plan here described has resulted from conferences between the Army, Navy, War Manpower Commission, and American Council on Education. The plan will be undertaken by the first three of these through a joint committee, with the final decisions in controversial matters being settled by the War Manpower Commission. Although it has been stated that the Army and Navy plans are similar, all data available at present indicate that there is considerable variation in the two programs.

THE ARMY

Selection will be governed by standards used for officers' candidate schools and some additional standards of the American Council on Education. Selection will be made from enlisted men who have completed or are completing basic military training and, except for some of the advanced courses, are under 22 years of age.

There are also eight special groups the members of which will be given training under this plan, including the following:

1. Medical students in the enlisted reserve, who will be called to active duty and detailed to continue instruction.

2. Medical students commissioned in the Medical Administrative Corps who may resign commissions and enlist as privates, to be detailed in the same manner as medical students in the enlisted reserve.

3. Premedical students in the enlisted reserve corps, who will continue on inactive status until the first semester of 1943 and will then be detailed as above.

4. Medical and premedical students not in the enlisted reserve who are taking approved courses, who will be inducted in Selective Service before the first semester of 1943, will be placed on inactive duty for a semester and then detailed for further training as above.

Colleges will be selected on the basis of standards, equipment, adequacy of housing and messing facilities, and minimum Army overhead. The standard of adequate proficiency is to be determined by the Army and the American Council on Education. Initial tests to predetermine the suitability of selectees will be evolved. Standard curriculums will be set by the Army and the American Council on Education. Military training will be given to these students during these courses of instruction under a cadet system. The plan will go into effect in February 1943 under the Commanding General of the Service of Supplies.

THE NAVY

Selection will be made of those having potential officer qualifications. Selections will be from high school graduates or the equivalent, from the seventeenth to the twentieth birthday, and enrolled or inducted men from the seventeenth to the twenty-third birthday. They will become apprentice seamen or privates in the U. S. Marine Corps on active duty with pay and will be assigned to designated colleges. Some other groups will also enter the training program, including V-1 or V-7 reservists who are undergraduates and qualify as medical, dental and theological students, who will continue on active duty as apprentice seamen under instructions in an accelerated curriculum in approved schools and seminaries until the completion of their professional studies.

Selectees can indicate the preference of their colleges and the branch of the service which they wish to join, including the Marine or the Coast Guard. Adequate arrangements for such students will be provided by the colleges under contract with the Navy, which will designate the number of students for the institution and the cost of maintenance of each student. The plan will be carried out under one naval officer in each institution who will issue instructions as to discipline and routine. Outlines of curriculums will be released by the Bureau of Navy Personnel. Credits will be allowed for scheduled courses which have already been completed and substitution of courses permitted.

A special required minimum for premedical students is similar to standard premedical requirements of medical schools. If the students are qualified at the termination of their course, they will be commissioned in the appropriate reserve. The Navy has issued special details for the correlation of this program with existing programs and specific directions for those who are now in V-1, V-5 and V-7 reserves, Naval ROTC, or who are probationary commissioned students.

ARMY

TROPICAL MEDICINE SPECIALISTS

More than a hundred medical officers were graduated from the Specialists' Course in Tropical and Military Medicine at the Army Medical School, Washington, D. C., Dec. 12, 1942. Col. Richard P. Strong, director of the course and emeritus professor in tropical medicine of Harvard University, delivered the address. The diplomas were presented by Lieut. Col. Thomas T. Mackie, executive officer of the course. Col. George R. Callender, director of the Army Medical School, presided. The subcommittee on tropical medicine of the National Research Council of the National Academy of Sciences, of

which Dr. Henry E. Heneveld is chairman, cooperated in preparing the curriculum and in presenting a list of names of qualified specialists from which to select lecturers. This is one of many such courses recently completed at the Army Medical School. The next class, which will begin the course at once, will comprise more than a hundred medical officers as well as a group of civilians who are on the faculty of various medical schools and have been granted special permission to attend this course. The Markle Foundation is underwriting the expenses of the visiting medical school faculty members and is also assisting in making available to the

medical colleges instructional material for use in the undergraduate teaching program in tropical medicine

The faculty for this course comprises especially qualified officers from various corps in the Army Medical Department, the Navy Medical Department, the U S Public Health Service and a civilian group appointed by the Secretary of War. The group from the Navy Medical Corps includes Rear Admiral Edward R. Stitt, retired, formerly Surgeon General of the Navy, Capt. Paul W. Wilson and Comdr. Leroy D. Fothergill. The group from the Public Health Service includes Drs. Edward Francis, Rolla E. Dyer, Louis L. Williams, Charles Armstrong, William G. Workman and Carl Larson. The civilians who thus far have participated as lecturers were Drs. Marshall A. Barber, Fred C. Bishopp, Mark F. Boyd, Walter Clarke, Lowell T. Coggeshall, William W. Cort, Ernest C. Faust, Thomas Francis Jr., William M. Mann, Henry E. Melaney, Elmer D. Merrill, Aristides A. Moll, Drs. John Scudder, Tom D. Spies, Max Theiler, Fred D. Weidman, Herbert C. Clark, E. Harold Hinman, Karl F. Meyer, George C. Shattuck, William H. Taliaferro, Ernest E. Tytzer and Mr. William E. Riter.

In addition, special lectures were included in these courses when possible, and these have been given by Col. Frank S. Gillespie, British medical liaison officer, Medical Field Service School, Carlisle, Pa.; Major Gen. Alexander Gordon Biggam, chief adviser to the Director General, Medical Services, British Army; Col. N. Hamilton Fairley, director of medicine, Australian Army; and Dr. C. G. Pandit, Kings Institute, Madras, India.

COORDINATION OF INTERNSHIPS WITH THE ACCELERATED MEDICAL PROGRAM

The Surgeon General, U S Army, has issued general suggestions and recommendations pertinent to closer cooperation between hospitals approved for internship and the medical colleges under the accelerated medical program. The Surgeon General is loath to recommend that a graduate physician of an approved school be called to active duty with the armed forces prior to completion of a twelve month general rotating internship. It is obvious that if the hospitals approved for internships do not cooperate with the accelerated program it would lose its effectiveness in releasing men for duty with the Medical Corps as soon as anticipated. There is now an urgent need for young, physically qualified medical officers for field troop duty.

Original directives from the War Department indicated that graduates were allowed twelve to eighteen months for completion of essential internships. In many instances interns have interpreted this directive as being authority to utilize the additional time for hospital training before beginning the twelve month rotating internship. This has also allowed hospitals which customarily start their intern classes on or about July 1 of each year to maintain original schedules. It is believed that each hospital should establish a schedule of internships commencing on or about April 1, 1943, available to those who graduate in March 1943 under the accelerated medical program and thereafter as students graduate.

This obviously results in the doubling up of those who have not yet completed their twelve months beginning July 1, 1942, but it is hoped that these interns can be used in approved affiliated internships or in the capacity of subresidents to assist in the orientation of medical school graduates of March 1942. The most recent information available of the interns' situation indicates that there are excessive position vacancies over the supply of available interns.

Unless the situation demands it, the War Department does not desire to shorten the period of internship to less than the twelve months required. However, under the increasing pressure of our military needs it is necessary to expect graduates to be immediately available, if physically qualified, twelve months from the time of their graduation. The War Department does not feel that the eighteen months is necessary for completion of a twelve month internship, and this time will therefore no longer be allowed.

It is hoped that all interns will be trained in the rotating type of internship for the twelve month period, that is, one which

provides training in medicine, surgery, pediatrics and their related subspecialties together with experience in laboratory and roentgenologic diagnosis. It is desired that house officers' positions be filled by those individuals not physically fit for military duty and those who are over age for troop duty. By following this procedure and increasing the duties of house officers and the essential staff membership, it is believed that a greater proportion of each year's intern class will be made available for active military duty.

Attention is invited to the new War Department directive precluding the appointment of senior medical students or interns as medical officers, Army of the United States, until within sixty days of their proposed active duty date. Such students and interns are protected from call to active duty by the War Department by:

- 1 Selective Service agreement
- 2 Medical Administrative Corps commissions
- 3 Commissions as Reserve Line officers, which they will receive on graduation from college.

This is accomplished under the authority of the War Department, A G O letter dated May 8, 1942, subject "Commissions for Medical Students," the main purpose of which is to protect the essential medical training program.

RANK ON INITIAL APPOINTMENT

The Surgeon General of the Army has published from time to time detailed information concerning policies governing the initial appointment of physicians as medical officers, and dentists as dental officers.

FIRST LIEUTENANT ONLY FOR MEN UNDER 38

Because of changes occurring in the military situation and in the civilian requirements, it is contemplated that changes will be required in the standards for the initial grade of appointment of medical officers. It is anticipated that in the near future eligible physicians under the age of 38 years will be appointed in the grade of first lieutenant only and that physicians in the age group 38 to 45 will be appointed in numbers and in the grades for which position vacancies exist.

There is no acute need for medical officers under the age of 38. Applications are being solicited in those localities where physicians may be designated by the Procurement and Assignment Service as available for military service.

Appointments of medical and dental officers by medical officers recruiting boards have been discontinued, however, the boards now active are to continue soliciting applications. All applications are forwarded to the Surgeon General for final recommendation of appointment.

MEDICAL INSPECTION OF SOUTHWEST PACIFIC AREA

Rear Admiral William Chambers, M C, U S Navy, recently returned from a tour of inspection in the South and Southwest Pacific. In his thirty-six day trip made entirely by war, Admiral Chambers visited dressing stations on Guadalcanal, saw marines under treatment at hospitals in the New Hebrides and viewed the activities of the hospitals which the Navy has erected in New Zealand. The Surgeon General of the Navy, Rear Admiral Ross T. McIntire, M C, recently disclosed that the mortality rate among wounded evacuated from the Solomons to mobile hospitals in the South Pacific was only 1 per cent for the first thousand men, which compares favorably with the normal expectancy of at least 5 per cent. The major share of credit for the low mortality in the Solomon campaign is given to the well equipped hospitals, the efficiency and fortitude of doctors and hospital corps men, blood plasma, sulfonamide compounds, tetanus toxoid and the speedy evacuation of the wounded. Ambulance planes also were given credit by Admiral Chambers, who said that each load carries as many as 11 litter patients and 4 or 5 sitting patients in addition to a medical officer, a pharmacist's mate and the crew. The situation is encouraging. The incidence of true dysenteries is low, and only 1 case of gas gangrene occurred on Guadalcanal while Admiral

Chambers was there. To illustrate that Navy doctors and hospital corpsmen attached to the Marines go where the fighters go, he said that two hands could be used to number our troops on Guadalcanal who have to use individual first aid dressings on themselves. Almost invariably when a Marine is wounded there is a surgeon or pharmacist's mate nearby. Admiral Chambers paid high tribute to Capt T. Brown, Medical Corps of the Navy, Marine divisional surgeon on Guadalcanal, and Capt Joel J. White, Medical Corps of the Navy, Commander of the advance hospital at Espiritus Santo, in the New Hebrides. This evacuation hospital, one of several in the Southwest Pacific to which wounded are flown, he said, is a stopover pending transfer of casualties to mobile hospitals southward by hospital ship.

EVACUATION HOSPITAL NO 14 ON ACTIVE DUTY

THE JOURNAL, Dec 12, 1942, page 1221, published an item entitled "Eight New York City Hospital Units on Active Duty" in which it was erroneously stated that U S Evacuation Hospital No 14 (City Hospital Unit) was not on active duty. The information on which this item was based was from the New York Times of November 22. The commanding officer of Evacuation Hospital No 14, Lieut Col Paul K. Sauer, writes that this hospital is at present on duty at Camp Claiborne, Louisiana, and that during the maneuvers, lasting one hundred and five days, this hospital, which is established completely in tents, treated 4,664 cases, among which were 221 major operations and 533 minor operations.

NAVY

EXPANSION OF PROGRAM FOR TRAINING NAVAL MEDICAL OFFICERS

Recommendations on expansion of the program for training naval medical officers in special fields were taken under advisement by Rear Admiral Ross R. McIntire, Surgeon General of the Navy, after a two day conference held December 10-11 at the Bureau of Medicine and Surgery. Submitted by the board of honorary consultants at the conclusion of the meeting, the report proposes:

1 Training of brain surgeons in naval hospitals, under Navy surgeons, with civilian hospitals and teaching personnel being utilized only if limited facilities make this step necessary.

2 Increasing the number of skilled anesthetists, to be achieved in part by training and utilizing medical officers of the Women's Reserve. (The commissioning of sixty women medical officers in the WAVES has been authorized, such officers to be assigned to Women's Reserve training schools and stations.)

3 Supervision of optometrists by ophthalmologists — naval surgeons whose specialty is the eye.

Training of more medical officers in chest surgery, continued emphasis on physical therapy and the exercise of care in diagnosing neuroses also were urged by the consultants, whose report was drafted by Dr. Frank H. Lahey, Boston, head of the Lahey Clinic and chairman of the Procurement and Assignment Service.

Others attending the conference were Dr. Donald Church Balfour, director, Mayo Foundation, Rochester, Minn.; Dr. George W. Crile, director, Cleveland Clinic Foundation; Dr. Walter E. Dandy, professor of neurosurgery, Johns Hopkins Medical School; Dr. Oswald L. Lowsley, New York; and Dr. Willis B. Morse, Salem, Ore.; Dr. Wilbur A. Sawyer, New York, director, International Health Division, Rockefeller Foundation; and Dr. Meyer Wiener, St. Louis, professor of clinical ophthalmology, Washington University School of Medicine. Dr. George W. Crile was the only member of the board not present, because of illness.

MISCELLANEOUS

BRITAIN THANKS UNITED STATES DOCTORS FOR THEIR AID

At a luncheon given in honor of the heads of the United States and Canadian army medical services in England at St. Dunstan's, famed British home and training center for the blind, the minister of health, Ernest Brown, expressed Britain's gratitude to those American doctors who generously gave their services to Britain during the early days of the war. He described how a number of American doctors came at their own expense and without remuneration to help in British general and special hospitals in the earliest days of the war, and more arrived after the collapse of France. British medical facilities were open to the United States forces when they began to reach Britain, and it was arranged that any service personnel and other American nationals needing treatment should be accommodated in British emergency hospitals. Five new fully equipped hospitals were given over to the Americans and eight hospitals to the Canadians by the Health Ministry. Mr. Brown said that arrangements have been made at St. Dunstan's for its hospital and training center to care for blinded American soldiers awaiting evacuation, while Americans would treat British casualties across the Atlantic similarly.

ASCORBIC ACID (VITAMIN C) PLACED UNDER ALLOCATION CONTROL

Ascorbic acid (vitamin C) was placed under allocation control, December 15, through the issuance by the Director General for Operations of General Preference Order M-269. Development of the use of vitamin C in food and medicinal production for the armed forces was the primary cause for the action, as production was formerly geared to meet pharmaceutical needs. The present production does not meet current

estimated requirements, and, although production capacity is being increased, demands for 1943 probably will be more than double the 1942 figures. Enough will be available, however, for essential civilian use. Vitamin C is used both by the armed forces and by civilians in the prevention and treatment of scurvy and other deficiency diseases caused by lack of sufficient quantities of this vitamin. The Quartermaster Corps is using large quantities in K and Jungle rations, and there is also a substantial demand for lend lease requirements. Sorbitol, recently placed under allocation control, is one of the principal raw materials needed for the production of vitamin C.

ARMY-NAVY E AWARDED TO WINTHROP CHEMICAL COMPANY

About a thousand employees and distinguished guests attended ceremonies at the plant in Rensselaer, N. Y., and at the offices in New York of the Winthrop Chemical Company, at which the Army-Navy E was presented to the Winthrop Chemical Company, which is manufacturing many vital drugs for the armed forces, among which is atabrine, synthetic substitute for quinine in the treatment of malaria. Atabrine is being manufactured in the United States today, said Dr. Theodore G. Klumpp, president of the company, at a rate of nearly one billion tablets a year. The flag was accepted for Winthrop's plant at Rensselaer by the plant superintendent, Dr. A. E. Sherndal. Dr. Klumpp in New York accepted the flag on behalf of the management. The principal speakers at the ceremonies were Brig. Gen. Charles C. Hillman of the Surgeon General's Office, Washington, D. C.; Rear Admiral Charles S. Stephenson of the Bureau of Medicine and Surgery, U. S. Navy; Dr. Morris Fishbein, editor of THE JOURNAL; and Lowell Thomas.

ORGANIZATION SECTION

OFFICIAL NOTES

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES, NOV. 19 AND 20, 1942

A two day meeting of the Board of Trustees was held in November, preceded by a full day meeting of the Executive Committee.

A considerable part of the first day was devoted to a conference with representatives of the three national hospital associations for a discussion of problems of mutual interest. At this conference a committee consisting of Dr. James A. Hamilton and Dr. Bert W. Caldwell representing the American Hospital Association, Mr. Edgar Blake Jr. representing the American Protestant Hospital Association, Rev. Alphonse M. Schwitalla representing the Catholic Hospital Association and Dr. Ernest E. Irons and Dr. R. L. Sensenich of the Board of Trustees was appointed to prepare a preliminary draft of principles differentiating between the services that may be included in plans and in hospital bills and those that may not be so included.

ELECTIONS AND APPOINTMENTS

Dr. Mont R. Reid was elected to the Committee for the Protection of Medical Research and to serve as vice chairman.

Dr. R. A. Hatcher was appointed an honorary life member of the Council on Pharmacy and Chemistry with the privilege

of the floor but without vote, and Dr. R. P. Herwick, chief of the Drug Division of the Food and Drug Administration, Washington, D. C. was elected to succeed Dr. Hatcher as a voting member of the Council.

A Committee on Student Health was appointed comprising Dr. J. E. Ravercroft, Princeton, N. J. (chairman), Dr. A. V. Bock, Cambridge, Mass., Dr. Ruth E. Boynton, Minneapolis, Dr. Frank B. Kelly, Chicago and Dr. Oswald Nickols, Anderson, Stanford University, Calif.

WAR DAMAGE INSURANCE

The Board approved the purchase of war damage insurance to cover the headquarters of the Association, including buildings, machinery, equipment and inventories.

DATE OF MEETING OF HOUSE OF DELEGATES

The Board confirmed its prior vote that the first meeting of the House of Delegates be held on June 7, 1943.

MISCELLANEOUS

Considerable time was devoted to the matter of investments, and to other matters on which no definite action was taken and which will, without doubt, receive further consideration at a later date.

MEDICAL ECONOMIC ABSTRACTS

EXPANSION OF CALIFORNIA PHYSICIANS' SERVICE

The California Physicians' Service is steadily expanding the scope of its work into new fields. Some of these new fields are described in *California and Western Medicine* for November. The services had already undertaken the medical care of migrant agricultural workers, which is financed and its nonmedical features managed by the Farm Security Administration. The development of war industries has created a new migratory problem involving at least 150,000 workers. The Federal Public Housing Authority has constructed housing projects for these workers mostly in new areas which formerly had only a small population. Naturally physicians, hospitals and other medical facilities were lacking in these areas.

"The California Physicians' Service has been considering the problem for several months, and has offered a plan to the Federal Public Housing Authority to meet this need. In approaching the subject, several fundamental factors had to be considered:

- '1 How to conserve the time of the already busy physicians
- '2 How to bring in more physicians to care for the increased population
- '3 How to relieve the load on the already overburdened hospitals

"In May of 1942 the California Physicians' Service experimented with a plan in the Linda Vista Project in San Diego. The entire responsibility for developing a medical care program was assumed by C. P. S. Through its sales force an attempt was made to enroll families throughout the project in a prepaid medical care program. When a sufficient number had enrolled

and adequate financing was in sight then doctors and nurses would be placed on the project to serve the residents."

The sales cost in this experiment was found to be excessive and the demand for prepaid medical care was lacking. Nevertheless the placing of additional physicians by the California Physicians' Service did relieve the emergency load on the San Diego physicians.

"When the need for medical care became apparent in other projects throughout the state and C. P. S. was asked to suggest ways and means of meeting the situation. Members of C. P. S. staff have been in constant consultation with the staff of the Federal Public Housing Authority and with representatives of the United States Public Health Service.

The new plan includes the responsibility of the Federal Public Housing Authority to enroll members in California Physicians' Service on a voluntary prepaid basis. Dues are collected when rent is paid. This permits the California Physicians' Service to concern itself with supplying necessary physicians and nurses and to arrange for hospitalization with Blue Cross Hospital Associations. This plan is now being developed in the new housing project in Marfan City. There are only two physicians and no hospital closer than 15 miles to this area, in which approximately 7,000 new residents will be introduced. This is another example of the collaboration of the medical profession and various governmental agencies.

The California Medical Service is also cooperating with a rural health program involving farm families with a net income of \$2,000 or less. It is expected that about four thousand farm families in Tulare County may be included in this program. Steps are also being taken to establish a similar plan in Fresno County.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Changes in Faculty at Stanford—Dr. William E. Stevens recently retired from the faculty of Stanford University School of Medicine, San Francisco, with the title associate clinical professor of obstetrics and gynecology emeritus. Dr. Stevens graduated at the Medical Department of the University of California in 1899 and has been a member of the faculty at Stanford since 1919. New appointments to the faculty include those of Drs. Henry Dean Brainerd as clinical instructor in medicine and pediatrics, James B. Irwin as instructor in neuropsychiatry and Robert P. Watkins as clinical instructor in bone and joint surgery, all of San Francisco.

"Impostor Phillips" Sentenced to Five Years—Arthur Osborne Phillips was sentenced to a term of five years in a federal penitentiary, December 10, after pleading guilty to falsifying government records to secure employment as a CCC physician. According to the San Francisco *Call Bulletin*, Federal Judge Martin I. Welsh meted out terms of five, three and three years on the three of four counts in a grand jury indictment to which Phillips pleaded guilty but ruled that the sentences should run concurrently. Phillips had been in the Sacramento county jail since his release on November 27 from the Butte county jail where he had been serving a nine months sentence for practicing medicine without a license at Enloe Hospital, Chico, and for being a former convict in possession of a gun. He had been paroled to federal authorities after the Butte County board had decided to withdraw their hold on him since he was sought by the federal government. Phillips, who was reported to have admitted that he performed thirty-two appendectomies since September 1941, was classified as a surgeon at the Brush Creek CCC camp before joining the staff of Enloe Hospital. It was stated. A complete record of Phillips's activities was published in *THE JOURNAL*, Sept. 12, 1942, page 145.

DELAWARE

Cancer Work Extended—At a meeting of the executive committee of the Delaware State Committee of the American Society for the Control of Cancer the constitution of the state group was amended to broaden the scope of its activities. In addition to its educational purposes the group will now aid patients in financial straits to receive proper diagnosis or treatment, assist in the establishment, development or maintenance of hospital clinics, laboratories or other facilities for the care of cancer patients, and generally carry on cancer control activities except the actual treatment of patients or actual operation of hospitals, clinics, laboratories or other facilities for such treatment. Rather than launch new projects at this time, particular attention will be given to the plan to render financial aid to special cases started more than a year ago. A simple method of procedure has been evolved whereby county commanders of the field army have been given a drawing account, and cases referred to them will receive immediate attention. Cases must be presented by accredited physicians and receive the approval of either the county chairman or some other medical member of the executive committee. Physicians are asked to cooperate with the state committee by investigating causes of delay in cancer treatment. The state medical journal points out that if it is financial worry which deters the patient the case should at once be reported to the county commander of the field army. The three county commanders are Kent Mrs. Lincoln Clayton, Dover; New Castle Mrs. William N. Cann, Wilmington; Sussex, Mrs. Topp M. Heath Frankford. The county chairmen of the executive committee are Drs. Clarence J. Prickett, Smyrna; Charles E. Wagner, Wilmington; and John Roscoe Elliott, Laurel. The state headquarters are located at the Delaware Academy of Medicine, Wilmington.

GEORGIA

Pediatric Meeting—The Georgia Pediatric Society held its annual scientific meeting in Atlanta, December 10. The afternoon session will be in the Biltmore Hotel and the evening session at the Academy of Medicine. The speakers included:

Dr. Alexander A. Weech, Cincinnati: Significance of Protein in the Diet and Cortical Maturation and the Development of Behavior in Infants.

Dr. Meredith T. Campbell, New York: Persistent Urinary Infection in the Young and Surgical Treatment of Certain Common Urologic Conditions in Children.

Dr. Abraham Levinson, Chicago: Neurologic Disturbances of the Newborn and Value and Limitations of Spinal Puncture in Children.

ILLINOIS

Dr. Pettitt Named Chief of the Emergency Services—Dr. Herbert L. Pettitt, Morrison, who recently resigned as assistant state health director to resume private practice (*THE JOURNAL*, Nov. 7, 1942, p. 774), has been appointed chief of emergency medical services in the Illinois Defense Council. The position was formerly held by Dr. Roland R. Cross, Springfield, state health director. Dr. Pettitt will devote only part time to the position.

Chicago

Society News—The North Shore Branch of the Chicago Medical Society will be addressed on January 5 by Dr. Douglas N. Buchanan and Charles Anderson Aldrich, on "Diagnosis of Acute Cerebral Conditions in Children" and "Color Photography in a Pediatric Clinic" respectively. At a meeting of the Chicago Laryngological and Otological Society on January 4 the speakers will be Drs. Lawrence J. Lawson, Evanston, Ill., on "Carcinoma of the Eustachian Tube", Leopold B. Bernheimer, "Otolaryngological Neoplasms—Clinical report of cases," and Paul H. Holinger and H. James Bara, Hinsdale, Ill., "Bronchogenic Carcinoma—Diagnostic Studies in 150 Cases."

Lectures at Institute for Psychoanalysis—A series of lectures and seminars will be held at the Institute for Psychoanalysis. Registration should be made prior to January 5. The lectures for professional or lay groups will consist of "Introduction to Fundamental Principles of Psychoanalysis and Psychosomatic Medicine" by Dr. Franz G. Alexander and "Personality Development in Childhood and Adolescence" by Helen Ross, B.S., and Dr. George J. Mohr. For members of the Chicago Psychoanalytic Society and students of the institute the topics to be considered are mechanisms of the individual neuroses, Freud's interpretation of dreams, selected problems of technique, clinical conferences on children's cases, review of psychoanalytic literature and clinical conferences. Lecturers will be Drs. Alexander, Thomas M. French, Edward Weiss, Margaret W. Gerard and Helen Vincent McLean.

KENTUCKY

Addition to Tuberculosis Sanatorium—A 96 bed addition to the Waverly Hills Sanatorium, Waverly Hills, is now under construction at a cost of about \$160,000. The addition will serve to bring the beds available for Negroes with tuberculosis up to a level of about 2 per annual Negro death. This ratio is already achieved for white patients; it is reported. Funds are being supplied jointly by the city of Louisville and by Jefferson County. The sanatorium is administered by the Louisville and Jefferson County Health Department.

MASSACHUSETTS

Personal—Dr. Winthrop B. Osgood, Boston, has been appointed medical superintendent of the Memorial Hospital, Worcester, succeeding Dr. George H. Stone, who has resigned because of ill health.

Students to Serve as Hospital Aids to Relieve Shortage—Boston University students will serve as interns, kitchen workers and nurses' aides in Boston hospitals on a part time basis while attending college during the new year to help relieve the serious shortage of help in local institutions through a "hospital emergency service" sponsored by the University Student Defense Board. Students will register with the board indicating the hours they can spare each day for hospital work and will be assigned to institutions in Boston through the Boston Red Cross headquarters.

MISSOURI

Personal—Dr. John L. Myers, Kansas City, was presented with a wrist watch during the meeting of the American Academy of Ophthalmology and Oto-Laryngology in appreciation of his sixteen years' service as a section secretary of the academy.

Special Society Election—Dr. Elmer E. Glenn, Springfield, was recently chosen president of the Missouri Tuberculosis Association at its meeting in St. Louis and Dr. Herbert L. Mantz, Kansas City, and Newell R. Ziegler, Columbia, were named vice presidents. Drs. Jesse E. Douglass, Webb City; James Stewart, Jefferson City; and Jesse A. Stocker, Mount Vernon, were elected members of the executive committee.

State Board Reorganized—The Missouri State Board of Health was reorganized at a meeting in Jefferson City, December 7. Dr. Cleveland H. Shutt, St. Louis, was elected president and Dr. Charles H. Neilson, St. Louis, was elected president and Dr. James Stewart, Jefferson City, state

commissioner, was elected secretary. Prior to the reorganization of the board Dr. Stewart and Drs. Hardin M. Henrikson, Poplar Bluff, and Howard B. Goodrich, Hannibal, were chosen members of the board.

NEW JERSEY

New Rehabilitation Center for Women with Venereal Diseases—The state department of health has approved plans to use the former home of Mr. and Mrs. Charles A. Lindbergh, Hopewell, as a hospital and rehabilitation center for women infected with venereal diseases. The state accepted the Lindbergh home as a gift more than a year ago.

Society News—Dr. Clarence R. O. Crowley, Philadelphia, discussed "Anomalies of the Kidneys and Polycystic Disease of the Kidneys" before the Passaic County Medical Society on December 15. Major Henry A. Cotton Jr., Trenton, discussed "Psychiatric Problems in the Armed Forces" before the Morris County Medical Society at Greystone Park, October 15.

Intestinal Outbreak Among Infants—An intestinal infection attributed to a virus has affected 30 infants in the maternity ward in Holy Name Hospital, Teaneck, newspapers reported December 16. Two deaths occurred. The chief result of the ailment appeared to be dehydration. The infants were transferred to the pediatrics department of the hospital which has been isolated and closed to new cases but the maternity ward is accepting new cases under restrictions.

NEW YORK

Age of Physicians Attending Meetings—The Medical Society of the State of New York has issued a release on the comparison of attendance this year with last at district branch meetings covering the entire state and comprising postgraduate educational activities. In 1941 the attendance at corresponding meetings of physicians between 45 and 54 years of age consisted of 25.21 per cent of the total in 1942, 30.81 per cent from 55 to 64 years, 16.15 per cent in 1941 and 22.56 in 1942. Among those from 65 to 74, 9.79 per cent in 1941 and 15.66 in 1942. In the group 75 to 84, 1.56 per cent in 1941 and 2.53 in 1942.

The Kenny Technic—Dr. Philip M. Stinson, New York, will deliver a lecture, January 5, on "The Early Treatment of Poliomyelitis with a Description and Evaluation of the Kenny Technic." The meeting will be a joint session of the Onondaga County Medical Society and the Syracuse Academy of Medicine under the auspices of the state medical society and the state department of health. On December 15 the Albany County Chapter of the National Foundation for Infantile Paralysis sponsored a free demonstration of the Kenny method. Dr. Don W. Gudakunst, medical director of the National foundation, New York, was the principal speaker.

Safeguard Against Accidents—The New York State Public Welfare Council has adopted an amendment to the sanitary code effective March 1, prohibiting the sale, distribution or use of any poisonous substance in an exterminator or insecticide unless the container bears a label legibly and conspicuously printed with the words "Poison" and the symbol of the skull and crossbones in red ink followed with the words "Caution—this exterminator or insecticide contains [state the name of the poison], a deadly poison, together with the antidote and treatment therefor and the name and address of the manufacturer or packer, and the words "poison," "caution" and "antidote" in block type of a larger size than the other wording. Insecticides or exterminators containing a fluoride shall be colored milk blue as designated by Ridgeway's Color Standards and Nomenclature and if sold at retail in quantities of 5 pounds or less the container thereof shall be of a nonrefillable type. The amendment was adopted as a safeguard against accidents such as the one that occurred recently at the Oregon State Hospital, Salem (THE JOURNAL, Nov. 28, 1942, p. 1050). Other examples cited to account for the new amendment were an outbreak in an upstate institution of 69 cases of food poisoning, which was traced to the accidental introduction of sodium fluoride into chocolate pudding and twelve fatal poisonings in the state of Maryland, which were the result of mistaking sodium fluoride for pancake flour.

New York City

County Society Approves Plan to Examine High School Boys—The Medical Society of the County of Kings has approved a plan inaugurated by the board of directors of the Society of New York whereby high school boys 16½ years and older, the preinduction age group, are expected to go to their family physician for a thorough physical examination preparatory to permitting these pupils to engage in a physical fitness program. Every effort will be made by the high schools

to induce these boys to obtain the physical examination from their family physician, but, in the event that some boys have no private physician and cannot pay the usual examination fee, volunteer physicians will be asked to make the examination in their offices. The plan is only for older boys and only for the duration. A roster of physicians offering to participate in the plan is being prepared by the director of medical activities of the Medical Society of the County of Kings. Each high school will be given a copy of this roster and each boy will be given an opportunity to select his own physician. Each high school will assume the responsibility for the follow-up care of defects discovered in the physical examination, through referral to the boy's own physician wherever possible, and if not possible to municipal clinics.

Health Education Conference—The 1942 Health Education Conference of the New York Academy of Medicine was held on November 17 with Dr. Malcolm Goodridge, then president of the academy presiding. Among the speakers were:

- Dr. Cassius H. Watson: The Wartime Intensive Industrialization in the Community and Its Health Implications
- Otto A. Bessey, Ph.D.: Food and Nutrition in the Home and in the World Place
- Dr. Leonard Greenburg: Disease and Handicap Detection and Control in Industry
- Dr. Lydia C. Baber: Mental Problems and Morale in Industry
- Mr. Harold R. Bixler: Educational Methods and Control of Accidents in Industry
- Dr. Fayo Childen: Summary and Review of Conference

Friday Afternoon Lectures—The regular series of Friday afternoon lectures which opened November 6 at the New York Academy of Medicine will include the following speakers:

- Dr. Russell C. Croze: January 8: Present Concepts and Treatment of Sinusitis
- Dr. David M. B. Worth: January 15: Shoulder Pain and Disabilities
- Dr. Milton C. Heller: January 22: Indications and Contraindications for the Newer Anesthetic Agents
- Dr. S. Bernard Worris: January 29: Modern Treatment of the Psycho-Neurotic
- Dr. Byron J. Stiefel: February 5: Intractable Pain—Surgical and Medical Treatment
- Dr. Robert I. Levy: February 19: Clinical Types of Coronary Insufficiency and Their Recognition
- Dr. Maurice Bruyer: February 26: Recent Advances in the Clinical Interpretation of Laboratory Data
- Dr. Philip Levine, Newark, N. J.: March 5: The Role of the Rh Factor in Fetal Death, Fetal Loss and Accidents and Its Importance to the Obstetrician
- Dr. Albert H. Mordue: March 12: Toxemia of Pregnancy
- Lieut. Comdr. Harold J. Harris, M.C., U.S. Naval Reserve, Westport, N. Y.: March 19: Brucellosis: Diagnosis, Differential Diagnosis and Treatment
- Dr. M. Henry Dow: March 26: Rheumatoid Arthritis and Its Treatment Including Cold Therapy
- Dr. Ralph Colp: April 2: Polychloestestromy Syndrome
- Dr. Henry I. Jaffe: April 9: Urinary Values in Relation to Bone Diseases
- Dr. Maurice Lenz: April 16: Value of Roentgen Therapy in Inflammatory Conditions

OHIO

Mcgrail Collection at School of Medicine—Friends of the late Dr. Emerson Mcgrail, associate professor of hygiene and bacteriology at Western Reserve University School of Medicine, Cleveland, are invited to contribute books to the Mcgrail Collection which has been placed in the students' room of the medical school. An appropriate bookplate has been designed by Dr. Louis J. Karnosh, associate clinical professor of nervous diseases at Western Reserve. Reprinted classics of medicine, monographs, biographies of physicians and scientists and semipopular books on medical subjects are especially desired. To avoid duplication donors are requested to phone or write to the secretary of the department of hygiene and bacteriology at the school. Dr. Mcgrail had been a member of the staff of Western Reserve from 1919 until his death on Oct. 21, 1941.

Night Service Plan Adopted by Medical Society—The Montgomery County Medical Society recently approved a plan for improving the night emergency medical care for patients, especially to take care of the emergencies arising at night among persons who have newly arrived in the locality or patients of the physicians who have joined the armed forces and have no medical connection. It is a war emergency plan only. Steps have been taken to have a night clerk in the city building to obtain all personal data between the hours of 10 p.m. and 6 a.m. the call to be referred by the clerk to the physician. Physicians will be stationed at the receiving ward of each hospital to receive the necessary hospital cases or to make house calls where absolutely necessary. This service is to be independent of the regular routine hospital service. Special stipulations cover the returning of the physician making the call. Written reports are to be made out for reference.

for the hospital, the Montgomery County Medical Society and the doctor who has to take care of the patient in the future. The society approved special minimum rates to care for every emergency. According to an announcement it is hoped that all physicians will be willing to participate in the plan, but the county society voted that the service of the physicians should be on a voluntary basis. The method of supervision and directing the program is to be under the guidance of the executive council of the society.

Lawyer Named Head of Cleveland Clinic Foundation—Edward C. Daoust, for more than twenty-five years a member of the firm of Garfield Daoust Baldwin & Vrooman, retired from the practice of law on January 1 to become the full time executive head of the Cleveland Clinic Foundation, which owns the Cleveland Clinic and its hospital. As foundation president Mr. Daoust will succeed Henry S. Sherman, president of the Society for Savings who will become president of the board. A. C. Ernst will continue as vice president and G. W. Gill and Remington Peck are secretary and treasurer, respectively. The clinic foundation is chartered as a nonprivate institution, operated for scientific, charitable and educational purposes. It employs 656 persons, including a staff of 69 physicians and surgeons. The principal properties are a 275 bed hospital and an eight story building that is devoted to experimental medicine and research. The cost of buildings and equipment exceeds \$3,500,000 and the foundation's endowment funds for medical research and charitable service are close to \$1,500,000. After the war the foundation plans to erect additional stories on the new Cleveland Clinic Building, which has foundations to support fourteen floors. The clinic was founded in 1921 by Drs. George W. Crile, William E. Lower and the late Drs. Frank E. Bunts and John Phillips. Mr. Daoust began the practice of law in Cleveland following his graduation from Yale University, New Haven, Conn.

OKLAHOMA

Personal—Dr. Hugh M. Galbraith, Oklahoma City, has been named a member of the medical advisory committee of the state medical association to the state department of public health, succeeding Dr. Moorman P. Prosser, Norman, who has entered military service.

Circuit Course in Internal Medicine—The fifth circuit in postgraduate medicine will open in Oklahoma City, Norman, Pauls Valley, Shawnee and Wewoka or Holdenville the week of January 11, according to the state medical journal. Dr. Luke W. Hunt, Oklahoma City, has been giving these courses throughout the state under the auspices of the Commonwealth Fund of New York. (THE JOURNAL, Feb. 21, 1942, p. 658). The lectures will cover the subjects of chronic arthritis and allied conditions, gastrointestinal diseases, disorders of the heart, cardiovascular renal disease, the anemias and blood dyscrasias, chronic nontuberculous pulmonary disease, diabetes mellitus, the uses and abuses of the sulfonamide compounds, nutritional diseases and deficiency states and endocrine disorders.

PENNSYLVANIA

Outbreak of Smallpox Among the Amish—A quarantine has been placed on an area of 40 square miles of Kishacoquillas Valley in an effort to halt an outbreak of smallpox believed to have stemmed from an Amish wedding, the New York Times reported on December 26. Seven Amish children, including 3 year old twins, were reported on December 25 to be suffering from smallpox, the first children stricken in the Amish farm section. On December 24 twenty adults between the ages of 50 and 70 were reported with the disease and all had been present at the Amish wedding several weeks ago. None of the child victims had been vaccinated and all are under school age. Many of the Amish adults had not been vaccinated. The inoculation is compulsory for their children, however, under state school laws. All social gatherings and Christmas church services were canceled in the valley of 8,200 inhabitants. State police guarded all roads leading from the area. The Lewistown farmers' market was forced to close leaving unfilled hundreds of orders for turkeys from Amish farmers. A woman guest from Ohio was suspected of having been the carrier. An Associated Press dispatch from Columbus, December 25 indicated that the woman was the wife of a minister who had been in good health before taking a three week trip with her husband into Pennsylvania, Delaware and Maryland to attend several weddings. She became ill with smallpox on her return late last month, it was stated. While members of the Ohio sect opposed vaccination, they submitted to immunization after 4 cases of smallpox were reported.

Philadelphia

Lectures on Legal Medicine—The Philadelphia County Medical Society announces a series of lectures on legal medicine, January 8 to March 12, to be conducted by the office of the coroner of Philadelphia County. The series includes:

Drs. Benjamin A. Gouley and Edward B. Krumhaar: Causes of Sudden Death.
William J. Connolly and Edward J. Burke: Identification.
Lieut. George R. Spangler: Ballistics.
Dr. Edward A. Strecker: Suicide.
Charles J. Swalm and James W. Tracey Jr.: Criminal Assault.
Dr. Elizabeth D. Wilson: Asphyxiation, Drowning and Burns.
Ivor Griffith, Ph.M. and Helen Ingleby, M.B.: Ancient and Modern Poisons.
Dr. Frank W. Konzelmann: Ancient and Modern Poisons (continued).
Dr. Abraham M. Ornstein: Insanity.
Judge Byron A. Milner: The Government and the Physician.

Pittsburgh

Society News—Dr. Joseph T. Beardwood Jr., Philadelphia, addressed the Allegheny County Medical Society, December 15 on "Management of Diabetic Emergencies" and Dr. Angelo L. Luchi, Wilkes-Barre, Diabetic Diets and Food Habits of the Nationalities.

Industrial Health and Hygiene—The University of Pittsburgh School of Medicine and the Allegheny County Medical Society are cooperating in a series of lectures on industrial health and hygiene. The series opened on December 10 and will continue on successive Thursdays. Drs. Frank S. Rosster, Swissvale, Pa. and Dr. Lawrence G. Beinhauer gave the first lectures on "Carbon Monoxide Poisoning" and "Occupational Dermatitis" respectively. On December 17 the speakers were Henry F. Smith Jr., Ph.D., on "Volatile Solvents" and Dr. George J. Busman, "Differential Diagnosis and Treatment of Occupational Dermatoses." The third pair of lectures will be given on January 7 by Drs. Charles F. Engel, Homestead, Pa., on "Electricity, Physiological Effects, Systemic and Local Treatment" and Charles F. Kutscher, Eye Injuries, Diagnosis and Treatment.

SOUTH CAROLINA

Faculty Changes at South Carolina—William A. Prout, Ph.D., has been named acting director of the school of pharmacy of the Medical College of the State of South Carolina, Charleston. He will continue as professor of operative pharmacy. Morris Belkin, Ph.D., formerly at Yale University School of Medicine, New Haven, Conn., has been appointed instructor in pharmacy at the school.

Founders Day Exercises—The Founders Day Exercises at the Medical College of the State of South Carolina, Charleston, were held November 4-5 in connection with a refresher course sponsored by the alumni association. Visiting lecturers included Drs. Robert B. Greenblatt, Augusta, Ga., John B. Youmans, Nashville, Tenn., Dr. Udo J. Wile, Ann Arbor, Mich., Luther E. Holt Jr., Baltimore, William B. Porter, Richmond, Va., Reginald Fitz, Boston, and James Heyward Gibbs, Columbia. Major George K. Lewis and Captain Alfred J. Suraci, M.C., U.S. Army. Dr. Howard T. Karsner, Cleveland, delivered the Founders Day Lecture at the annual banquet, on "Aortic Stenosis."

TENNESSEE

New Hospital in Memphis—The Thomas Frank Gailor Psychiatric Hospital and Diagnostic Clinic was recently officially dedicated as part of the John Gaston Hospital, Memphis. It will be staffed by the University of Tennessee College of Medicine and except for staff salaries operating expenses will be handled through the Memphis and Shelby County Health Department. City, county and state funds were used to finance the cost of \$515,000. Four floors of the six story building will be used as an outpatient clinic and two as a psychiatric hospital. Three floors of the hospital have 40 beds available 30 to be used for the care of temporary patients and 10 for teaching purposes. Dr. Theron S. Hill, professor of psychiatry at the University of Tennessee College of Medicine is director of the new hospital. Dr. Arthur F. Cooper, Memphis secretary of the Memphis and Shelby County Medical Society, has been named the first full time director of the outpatient portion of the new unit.

TEXAS

Professor of Dermatology Appointed—Dr. Chester N. Frazier, recently engaged in venereal disease control work at the Johns Hopkins School of Hygiene and Public Health, Baltimore, has been appointed professor of dermatology and syphilology at the University of Texas Medical Branch, Galveston. Dr. Frazier was formerly professor of dermatology and syphilology at Peiping Union Medical College, Peiping, China, where he had been a member of the staff since 1922.

University News—Dr Owen H. Wangenstein professor of general surgery, University of Minnesota Medical School Minneapolis, delivered the Alpha Omega Alpha lecture at the University of Texas Medical Branch, Galveston recently on the "Secretory Functions of the Appendix as a Factor in Appendicitis." At the banquet Dr Wangenstein discussed "Surgical Aspects of Peptic Ulcer." The staff and students at the medical branch were recently addressed by Dr Meyer Wiener, Coronado Calif professor of clinical ophthalmology emeritus, Washington University School of Medicine St Louis on "War Injuries to the Eye."

GENERAL

Katharine Lenroot Awarded Medal—The Rosenberger Medal for 'notably great service in the promotion of human welfare' was awarded to Katharine Lenroot Washington chief of the Children's Bureau U S Department of Labor during the two hundred and eleventh convocation of the University of Chicago in Rockefeller Memorial Chapel December 18.

Academy of Pediatrics Opens Membership to Latin Americans—At the annual meeting of the American Academy of Pediatrics in Chicago, November 4-7 it was decided to develop region 5 of the academy to consist of the Latin American countries, members to be taken in practically on the same basis as members from the United States. On November 6 fifteen Mexican pediatricians who had applied were accepted to form the basis of a group in Mexico. According to Dr Clifford G. Grulee, Evanston Ill. secretary of the academy steps are now being taken to develop groups in each of the Latin American countries from which communications have already been received. The names of the Mexican pediatricians who were recently elected to membership are Drs. Alfonso G. Alarcon, Rigoberto Aguilar Pico, Alejandro Aguirre Torres, Enrique Bar Dresch, Hernando Lamberto Castañeda, L. Federico Gomez Santos, Deofilo Gonzalez C., Carlos Herrera Romero, Fernando Lopez Chies, Jesus Lozoya Solis, Ismael Martinez Sotomayor, Jorge Muñoz Tunbull, Agustin Navarro Hidalgo, Roberto L. Sanchez Messick and Rafael Soto Allande all of Mexico, D. F.

Reorganization of International Society of Surgery—The headquarters of the International Society of Surgery has been provisionally transferred from Brussels to the United States and set up in the Inter-American Division of the New York Academy of Medicine in accordance with recent action of the council of delegates. In explaining the need for the change, Dr Rudolph Matas, New Orleans acting secretary and treasurer, stated:

The German occupation of Belgium and the Nazi devastation of the rest of Europe and all the other war-torn nations had virtually restricted the international relations of the society to the Western Hemisphere where its fellowship is widely spread through its affiliated branches in North Central and South America.

The Executive Committee of the United States Division the largest most active contributor to the transaction felt it their duty conjointly with their Latin American colleagues to rescue the society from the perils of the European configuration. The first steps were taken in November 1941 at Boston but no final action could be taken to transfer the official sanction in Brussels to America without the concurrence and approval of all the affiliated branches in America.

The transfer was voted by the delegates from all the affiliated societies of the Americas representing Argentina, Brazil, Canada, Cuba, Ecuador, Guatemala, Mexico, Paraguay, Peru, the United States, Uruguay and Venezuela. The affairs of the society will be administered by an executive committee composed of Colonel Elliott C. Cutler M. C. U. S. Army chairman in absentia, Dr. Eugene H. Pool New York, Dr. Arthur W. Allen Boston and Dr. Matas. Dr. Pool is acting chairman for Colonel Cutler and Dr. Jose Arce dean of the University of Buenos Aires is acting president in the absence of Prof. Leopold Mayer, Brussels detained in Belgium by Nazi compulsion, according to *Science*. A revision of the constitution prepared by Dr. Matas was adopted in November and a representative group of fellows from New York and elsewhere signed the act of reorganization as witnesses of the signing of the act by the delegates of the governing council. The Inter-American Division of the New York Academy of Medicine is under the direction of Dr. Mahlon Ashford New York. Dr. Enrique J. Cervantes, New York assistant secretary-treasurer of the executive committee of the international society, editor of *América Clínica*, the official organ of the society and secretary of the Hispanic-American Medical Society is available in the division's offices to render service to the fellows of the society and to medical visitors from the Latin American countries.

Examinations in Obstetrics and Gynecology—The next written examination and review of case histories (part I) for all candidates will be held in various cities of the United States

and Canada on Saturday, February 13, at 2 p. m. Arrangements will be made so far as possible for candidates in military service to take the part I examination (written paper and submission of case records) at their places of duty, the written examination to be proctored by the commanding officer (medical) or some responsible person designated by him. Material for the written examination will be sent to the proctor several weeks in advance of the examination date. Candidates for the February 13 part I examination who are entering military service or who are now in service and may be assigned to foreign duty may submit their case records in advance of the aforementioned date by forwarding the records to the office of the board secretary. All other candidates should present their case records to the examiner at the time and place of taking the written examination. The Office of the Surgeon General of the U. S. Army has issued instructions that men in service, eligible for board examinations be encouraged to apply and that they may request orders to detached duty for the purpose of taking these examinations whenever possible. All candidates will be required to take both the part I examination and the part II examination (oral clinical and pathology examination). Candidates who successfully complete the part I examination proceed automatically to the part II examination which will be held in Pittsburgh May 19-25. Notice of the exact time and place of the examinations will be sent all candidates well in advance of the examination date. Candidates in military or naval service are requested to keep the secretary's office informed of any change in address. If a candidate in service finds it impossible to proceed with the examinations of the board, deferment without time penalty will be granted under a waiver or published regulations applying to civilian candidates. Applications are now being received for the 1944 examinations of the board. For further information and application blanks address Dr. Paul Ittus, secretary, 1015 Highland Building, Pittsburgh, Pa.

Activities at North China Drug Factory—During the first eight months of the current year 350,000 tubes of smallpox vaccine were manufactured at the "Guerrilla drug factory" in Northwest China according to a release from the United China Relief, New York. Credit is given largely to the work of this drug factory for averting a major smallpox epidemic, the release states. The factory was opened four years ago in the center of a plague belt where epidemics of typhus, diphtheria and typhoid are common. The plant is assisted financially by United China Relief. The smallpox serum is one of seventeen different serums now being produced in large quantities by the drug factory which also produces ten kinds of tablets, seven kinds of tinctures and twenty kinds of Chinese compounds. The drug factory is constantly expanding its list of drugs and medicines and increasing its output to provide the four International Peace Hospitals of the Northwest with necessary supplies many of which up to this time had to be smuggled through enemy lines. In Shensi where the drug factory is located, the area is rich in medicinal herbs and the factory's department of Chinese medicine is producing two hundred medicines based on native products. Many of the native herbs commonly used by herb doctors have been found to have the healing and corrective qualities claimed for them by these traditional medical men of China. In the department of western medicine ampules for injection are prepared from imported raw materials at a saving of 60 per cent over the cost of foreign finished supplies. The third division, the manufacturing department last year produced 5,000 pounds of absorbent cotton and 4,000 pounds of fine gauze. In addition to other products 1,000 pounds of tinctures have been produced monthly. Sodium chloride, sodium sulfate and other sulfur products much needed by the hospitals and mobile units, are now available. Besides preventive serums and life saving drugs, the drug factory is producing such products and by products as cod liver oil, phenol solutions and medicinal soaps. Most of the medicines are being prepared in tablets, pills, powders, solutions and tinctures instead of the ancient and bulky form of aqueous extracts. A search for substitutes for imported drugs is being carried on in the laboratory since one of the main problems of the Northwest has been and still is its inaccessibility because of blockades. Of the two hundred workers employed by the factory, China Aid Council reports that approximately one fourth are regularly instructed in chemistry, physics and pharmacology by the chemical engineers and the technical staff. All take part in management training and the aim is the establishing of other such cooperative centers throughout the area. The most urgent problems to be met are lack of sufficient technicians, adequate machinery and funds for maintenance and training.

London During a Year of Attacks from the Air

The report of the county of London medical officer of health and school medical officer for 1941, which has just been published, covers the second whole year of the war and for the first time gives a complete account of health conditions under the strain. During the heavy bombing of London in the first five months of 1941 the public health services were carried on under conditions of difficulty, but despite destruction of life and property they were never disorganized. No matter where the blow fell, new arrangements were speedily made and the work went on. When a hospital was partly or wholly put out of action, patients and staff were promptly transferred elsewhere. Temporary ambulance stations and school clinics appeared within a few days or hours after a loss. During the period of heavy air attacks the population of London fell considerably by evacuation. This, with the absence of any serious epidemics, made the reduced hospital accommodation quite sufficient. The practice of rapidly evacuating air raid casualties and other acutely ill patients from the London hospitals to others outside London was of great assistance in keeping beds available for casualties.

The aggregation of large numbers of persons in air raid shelters led to apprehension that epidemics would develop, but they did not. The number of deaths from all causes in 1941 was 43,537, against 57,459 in 1940. Diseases due to droplet infection might have been expected to increase, but the deaths from influenza, pneumonia and bronchitis were in each case less than in the previous year. Cerebrospinal fever also showed a reduction. It is remarkable that there were only 2 deaths from scarlet fever. In 1893 these numbered 1,415. Scarlet fever has now become a mild disease with a case mortality* below 1 per thousand. There was some increase in diphtheria. According to the usual biennial cycle there should have been an epidemic of measles in the winter of 1939-1940 but dispersal or some other cause broke the rhythm and the deaths numbered only 29, compared with 235 in 1938. Whooping cough deaths increased from 10 in 1940 to 111. Typhoid caused only 17 deaths, and no case was attributable to infection by water, despite frequent disturbances of the drainage systems by bomb explosions. There was a definite decrease in the number of admissions to mental hospitals, as in the last war. Inspections of school children and comparison with the same age groups in the prewar years showed no evidence of mental or physical deterioration.

Medical Aid to Russia

Mrs Churchill, president of the Red Cross Aid to Russia Fund, announces that despite many other demands on their charity the public has subscribed \$10,000,000. On returning from his visit as head of a British medical mission to Moscow, Sir Charles Wilson, president of the Royal College of Physicians, brought back a tremendous list of needs. Among the articles dispatched were blankets, first aid pouches children's clothes, 2 tons each of chloroform and ether 10,000 Kg of sulfanilamide, 50,000 Kg of chloramine 150,000 dissecting forceps, 77,000 hypodermic syringes, 200,000 ampules of strophanthin 18,000 scalpels, 60,000 surgical scissors 54,000 tourniquets 523,000 yards of rubber sheeting, 100 portable x-ray sets 30 tons of blood transfusion tubing and 30 tons of cocoa butter. For many of the articles special methods of production had to be introduced, and some instruments were manufactured for the first time in this country. The call for cocaine and procaine

hydrochloride, which had to be and was met, was for quantities which equaled three years' normal use in Britain. In addition to medical supplies, at the request of the British government, 400,000 woolen garments were sent to Russian refugees restored to regained territory.

Women Medical Students

During the academic years 1940-1941, of the 5,265 students of medicine and dentistry in the University of London 117 per cent were women. Three fifths of these were at the London School of Medicine for Women. In the other schools only 5 per cent were women. In the remaining universities of Great Britain, of 7,687 students of medicine and dentistry 21.4 per cent were women. During the war the total number of students has only slightly diminished—from 13,636 in 1938-1939 to 12,952 in 1940-1941, and the number of women has only slightly increased—from 2,013 to 2,261. In a letter to the *Times*, Prof. A. V. Hill (physiologist and member of Parliament) states that medicine and dentistry are professions particularly suitable for women especially in the coming important developments of public health services, maternity and child welfare, school medical and dental services and the women's services, and that many women are anxious to enter them but are rejected, particularly in London, not for any other reason than that they are women. The majority of the London schools refuse to accept them at all. If they took them in the same proportion as the provincial schools, there would now be five hundred more women students in London. Even the present shortage of manpower has not led the London schools to modify their policy. They have taken a large number of young men who had better be in the fighting services. Protesting against this position, Professor Hill suggests that the minister of labor should refuse to reserve any more men to begin the study of medicine in schools which do not accept women.

Medical Education in Municipal Hospitals

London already has twelve undergraduate medical schools as well as postgraduate schools. These are all attached to voluntary hospitals (so called because supported by voluntary subscriptions). But in recent years another important hospital system has arisen—the municipal hospitals, under the control of the London County Council, which are supported not by subscriptions but by taxes. They have no undergraduate medical schools attached to them, though they constitute the largest hospital system in the world, but they have already established an important postgraduate school. In a report submitted to the council by its general purposes committee the establishment of an undergraduate medical school is proposed. The report takes the form of the evidence given by the council to the interdepartmental committee on medical schools recently set up by the minister of health. The new school would be set up at one of the council's larger general hospitals and would utilize other hospitals and schools as required. It would become an internal school of the University of London, which would provide the teaching staff, or alternatively the council itself would be responsible for the direction of the school. It is claimed that the experience which the council has gained in seven years of administration of the British Postgraduate School should be of great value in the new scheme. The new school, unlike the other London schools, would be open to women as well as to men.

The council's interest in medical education arises from its position as the major health authority of London and the largest civilian employer of medical staff in the country and from the facilities offered by its hospitals, which number one hundred. For some years it has provided for certain clinical teaching—in obstetrics, fevers, psychiatry, venereal diseases and others—by the affiliation of its hospitals with the voluntary ones. Up to the outbreak of war, eleven of the medical schools were

linked with sixteen of the council's "acute" general hospitals, in which classes and demonstrations were conducted by the council's medical staff. Teaching in obstetrics is already given at ten of the council's hospitals to students from nine London schools. Plans are in hand for the teaching of psychologic medicine after the war in the council's mental health services. It is suggested that the service performed by the field of public health and social welfare should be brought more closely to the notice of medical students as a means of teaching them the wider aspects of social and preventive medicine and that the council's schools can do this. Finally, the report calls for greater coordination of postgraduate medical education in London.

Arrangements for the Care of Children of War Workers

The large number of women engaged in war work many of whom are married and have children, has created a new problem. To enable mothers with young children to undertake war work, about a thousand wartime nurseries have been established and five hundred more are in preparation. There are also four hundred special nursery classes for the children of war workers and nearly three hundred in preparation. In addition over a hundred thousand children under the age of 5 years are in ordinary elementary schools, and there are sixty-three nursery schools. But there are still many women whom industry wants for whose children there is no provision. The Ministry of Labor's solution is "child minder" schemes, which were brought forward some months ago, but few were started as there was a prejudice against them from fear that the children would be neglected. However, they have been a success in Birmingham, where they are known as the Children's Home Service. They are based on child welfare centers where the mother and the prospective "minder" are brought together. The latter has usually children of her own. The ministry pays her \$1.50 a week for each child on condition that it is brought to the center when required, and the mother pays \$2.50 and provides the rationed foods.

The Electroencephalogram in Criminal Trials

In 1929 Berger observed that electrodes applied to the normal scalp gave oscillations of potential of 10 per second on a recording instrument. This was subsequently confirmed by other observers. The oscillations are due to electrical activity of the cortical cells. It was subsequently shown that characteristic changes of rhythm occur in epileptic patients not only during the fits but between them. This fact has led to the electroencephalogram being used as evidence on the question of responsibility in criminal trials. A soldier who fired a rifle at a corporal pleaded that he had no knowledge of the affair and suffered a head injury a few hours previously. The attack was apparently without motive. An electroencephalogram showed abnormalities compatible with the head injury and he was discharged. In another case, in which a brutal and apparently purposeless murder was committed, the defense was that it was done in a period of postepileptic confusion. The evidence of epilepsy was tenuous but an abnormal electroencephalogram was produced. The medical witnesses said that an absolute diagnosis of epilepsy could not be made on this, as no subclinical attacks were seen, but it made the diagnosis likely. The man was found "guilty but insane" and so escaped capital punishment.

Funghi as Food

Before the war we imported two thirds of our food supply. The need to devote as much shipping as possible to the transport of munitions has reduced the amount of imported food to one third of our total supply, and the loss of the other third has been compensated by extension of our agriculture. We are

looking to sources of food growing wild which are ordinarily neglected, such as the edible fungi. Dr. John Ramsbottom, keeper of botany in the Natural History Museum, South Kensington, has called attention to them in a letter to the *Times*. This has led to more than four hundred letters, often accompanied by specimens, being received at the museum, and evidence has been obtained on the eating of forty different kinds, though the general public knows and uses only two kinds. The museum is anxious to spread a knowledge of the best and most easily recognizable edible species. To this end an exhibit of fresh specimens of both edible and poisonous fungi, supplemented with colored plates, is on view. Moreover, lectures are being delivered on the subject. It is emphasized that the popular traditional tests as to what is edible and what is not are quite unreliable. Such for example, is the belief that if a mushroom can be peeled it is edible. The deadly *Amanita phalloides* peels beautifully. Also the belief that all species which grow under trees are poisonous is wrong. If people would learn to recognize the best edible fungi and also the poisonous, a palatable food such as is commonly eaten on the European continent, would be saved from going to waste.

Sailors Leave Their Sick Beds to Fight

The epic story of the greatest convoy ever sent to arctic Russia which withstood a battle of four days, in which it was attacked by airplanes, surface vessels and submarines, has been told in the press. The principal medical officer stated that when the alarm sounded all the patients in the sick bay leaped from their beds to their action stations at the guns and, when the situation eased, returned to their beds. One of them who had some badly damaged ribs manned a gun forward. After the first attack he was asked by the medical officer how he felt. "Bit of a headache, sir, I could do with a couple of tablets," he replied.

Surveys of Hospital Services

As shown more than once previously in *THE JOURNAL*, the calm confidence with which the country regards the outcome of the war is proved by the various forms of planning for the future. The Ministry of Health is now carrying out its third survey of hospital services which covers northeastern England. The survey is in the hands of the Nuffield Provincial Hospitals Fund which was established as one form of the munificence of the automobile magnate Lord Nuffield. The trust has appointed Mr. H. J. Eason chairman of the General Medical Council, Dr. Vetch Carl, late health officer of Manchester, and Mr. W. H. Harper, house governor of Wolverhampton Hospital, to carry out the survey. Other surveys are to follow until the whole country is covered. Mr. Ernest Brown, minister of health, has stated that the first object of the surveys is to see how far each patient can as easily as possible obtain the best treatment of the kind he needs.

New Uniform for Nurses

For the first time in over sixty years the nursing uniform of the London Hospital has been changed. The new dress became necessary because the old one took about 6 yards of material, and today war rationing allows only 4½ yards. The familiar large Victorian "leg of mutton" sleeve has given place to a small puff sleeve. Soft collars and cuffs stitched with mauve or blue to match the frock and made from apron material take the place of starched collars and the sisters' cuffs. There is a new hat with the hospital badge stitched on the hat band and new overcoat in place of the old "London" cloak. Aprons will be worn only by sisters and nurses when on ward duty. During the war the sisters will wear their yard long cap tails only on special occasions. The changes mean that 1,680 fewer aprons and 10,686 fewer detachable sleeves will be worn during the year.

BRAZIL

(From Our Regular Correspondent)

Oct 31, 1942

American Trypanosomiasis in Brazil

Oswaldo Cruz and Carlos Chagas described in 1909 a new human trypanosomiasis affecting some poor peasants in the state of Minas Gerais, Brazil. The parasite has been named *Schizotrypanum cruzi*, and the new disease has been known as Chagas' disease or American trypanosomiasis. Since then acute and chronic cases of the disease have been described in almost all the countries of the Western Hemisphere, with the principal exceptions of Canada and the United States. However, naturally infected vectors (blood sucking bugs of the family Reduviidae) have been found in the states of California, Texas and Arizona, and a bug of the state of Florida (*Tritoma sanguisuga* Ambigua) was experimentally infected two years ago by A. Packham of the National Institute of Health. At the recent meeting of the eleventh Pan American Sanitary Conference, held in Rio de Janeiro, Dr. Carlos Chagas Jr. read a paper on the situation of American trypanosomiasis in Brazil. The evolution of the parasite in vertebrates (armadillo, opossum, dog, cat, guinea pig and rat) has recently been restudied and developed by Dias and Freitas, whose researches on the life cycle of *S. cruzi* have definitively established that, in the bug, the evolution takes place mainly in the posterior intestine, a fact of the greatest importance because it permits the normal transmission of the disease by the feces of the bug, full of the metacyclic forms of the trypanosome. After many negative results, some workers have succeeded in the transmission of the parasite through the bite of the insect, but this exceptional fact is explained by Dias as a consequence of the regurgitation of infective forms from the stomach. Dr. Carlos Chagas Jr. has established that the intracellular evolution lasts about five days. The initial focal proliferation of the trypanosomes has enabled Romãia, from Argentina, to raise the hypothesis of the entry of the parasites through the conjunctival membranes of the eye, a fact now considered well proved. The most recent studies have also demonstrated that *Schizotrypanum* has a great affinity for the reticuloendothelial system, and thus the protozoon is considered a primitive parasite of this system.

As *S. cruzi* cannot live in the exterior world through the direct transmission from bug to bug, because the insects are not naturally given to coprophagism and to cannibalism nor is there hereditary transmission of the trypanosomes in the bugs, the presence of infected insects in any area is a sure indication of the existence of vertebrate reservoirs of the parasites. Out of the twenty states of Brazil, in thirteen the natural infection of reduviids has been proved. The most numerous examinations have been made in the state of Minas Gerais, where, up to the present, 3,855 insects have been found naturally infected out of a total of 12,336, or 31.3 per cent. In Brazil, more than thirty different species of reduviids have been found naturally infected, and several vertebrates have been found as reservoirs of the trypanosomes. Among the domestic animals acting as reservoirs, the dog and the cat are important, since they are so closely connected with the poor peasants in the adobe and other primitive houses infected by the bugs. Among the sylvatic reservoirs the most important are the armadillos (*Dasypus novemcinctus*, *Dasypus hybridus* and *Euphractus sexcinctus*), which harbor parasites with nuclear index identical to that of the trypanosomes from man.

The majority of the human cases of the American trypanosomiasis observed by Carlos Chagas were chronic cases but in a few children he was able to recognize the acute form of the disease. The exact diagnosis was difficult, because it was necessary to base it on the finding of the trypanosomes in the peripheral blood, and the parasites are rather rare in this

medium. The venodiagnosis carried out by allowing uninfected reduviids to suck the blood in the suggestive cases and later trying to ascertain the presence of the parasite in the bugs, became an important diagnostic tool, but it was somewhat difficult to use. Some progress had also been made by the use of the complement deviation test, as devised by Machado and Guerreiro of the Oswaldo Cruz Institute. Some years ago Mazza and Romãia described what is now commonly named the Romãia sign, i. e. the unilateral strong palpebral edema and conjunctivitis, with definite ganglionic reaction, an important sign for the detection of acute cases. The cardiac form of the disease (the most common chronic clinical form) is characterized by a strong Machado-Guerreiro reaction and tachycardiac, bradycardiac, extrasystolic and arrhythmic symptoms. In no other disease is the myocardial process so intense as in the American trypanosomiasis. A striking fact is the finding of many cases of sudden death in small towns, in the areas affected by the disease. It is now well recognized that there is no connection between Chagas' disease and goiter, contrary to what Chagas himself emphasized in his early writings. In the state of Minas Gerais the geographic distribution of trypanosomiasis coincides with that of simple goiter, but in Argentina, for instance these areas of prevalence of the two diseases are entirely different.

Dogs as Healthy Carriers of Brazilian Typhus

The São Paulo state strain of typhus fever was related in 1932 by cross immunization by Lemos Monteiro, by Parker and Davis and by Dyer of the United States to Rocky Mountain spotted fever. The state of Minas Gerais type of endemic typhus, first recognized in 1934 by J. A. Monteiro and Octavio Magalhães, was proved in 1939 to be identical with the spotted fever virus (THE JOURNAL, Jan 10, 1942, p. 159). Thus there is only one strain of Brazilian typhus, and that one is identical with the United States spotted fever. Prof. Octavio Magalhães and Dr. Adyr Rocha of the University of Belo Horizonte, Minas Gerais, who have actively continued to work on the Brazilian typhus, profiting by several massive domiciliary foci of the disease, with 2, 4, 7, 9 and even 12 severe or slight cases in the same dwellings in rural areas around Belo Horizonte city. Their ideas about the epidemiology of the Brazilian disease are that it is quite different from the disease prevalent in the United States. They have insisted (*Brasil-med* 49:465 [May 25] 1935) that the Brazilian typhus has a different epidemiology, and among the particular epidemiologic features they have pointed to the importance of the dog as a carrier. They point to the fact that, since 1930, the dog has been shown to act as a healthy reservoir for the virus of the Mediterranean littoral typhus fever (fièvre boutonneuse). In this case the vector is a tick (*Rhipicephalus sanguineus*) which also transmits the disease hereditarily. Also Salles Gomes of São Paulo reported in 1933 that a tick (*Amblyomma ovale*), taken from a pet dog of a house where a few cases of Brazilian typhus had occurred, was infected, but no further significance was given to the fact. Magalhães showed that in Minas Gerais about 25 per cent of the patients had strictly domestic occupations, and many of them were young children. In September of last year Magalhães published a report of a small focus in a suburban house of Belo Horizonte, where, during the course of a few months, he recognized 1 severe and fatal case of typhus, 3 mild cases and 1 labeled "inapparent case," i. e. with no symptoms but presenting the virus in the blood. In 2 dogs and in several bedbugs (*Cimex rotundatus*) the presence of the virus has been recognized, and, what is more important, 1 of the dogs remained infective for forty days.

To investigate this subject fully, Magalhães and Rocha devised an extensive experimental study, the conclusions of which have been published in the *Brasil-medico* (56:370 [Aug 1] 1942). They worked with 139 dogs from different places in the state

of Minas Gerais 4 have been inoculated experimentally and 135 were naturally infected. The Weil-Felix test has been done with OX 19, OX 2 OX L, and OX K strains with the maximum results of 1 280 for the OX 19 and 1 640 for the other strains. The results of the Weil-Felix tests were as follows for the 135 cases of natural infection: 54 dogs from houses of the urban zone of Belo Horizonte 79 per cent positive, 76 dogs from houses of the suburban zone 90 per cent positive, 5 dogs from rural areas 87 per cent positive. Three of the 4 inoculated dogs gave a positive Weil-Felix reaction. It was possible to try to recover the virus from only 31 dogs. The blood of the dogs has been injected into guinea pigs and into rhesus monkeys with 11 positive results or 35.5 per cent. These studies emphasize the importance of pet dogs as natural carriers of Brazilian typhus, and the results are worth trying again in other places of the Americas as the virus of Brazilian typhus is not different from that of Rocky Mountain spotted fever.

Primary Bronchial Diphtheria

A case of rare localization of diphtheria has been reported by Dr Celestino Santos of the J C Rodrigues Hospital of Rio de Janeiro in a child 2 years old. The patient was feverish seeming to have a simple cold. On the following day he became asphyxiated, with a stridulous cough. The examination of the respiratory apparatus disclosed no abnormalities through percussion and auscultation. A careful examination of the throat the tonsils and the uvula was also entirely negative except for a slight hyperemia. Early on the third day the state of the patient became still worse and another physician suspected diphtheria injected 20 000 units of antitoxin and sent the child to an otorhinolaryngologist, who could find nothing more. The examination of specimens taken from the throat and from the nose was negative. The patient was subjected to tracheotomy but died a few hours later. The necropsy disclosed an extensive diphtheric patch in the bronchi, beginning to invade the pulmonary parenchyma. This is an extremely rare localization of diphtheria difficult to diagnose.

Alcoholization of the Mesoappendix

As a result of observations on 407 patients operated on for appendicitis in which the alcoholization of the mesoappendix was employed, Dr Henrique Smith concluded that this new method is a means of obtaining a painless period after the operation. The alcoholization produces no complications for as long as three years after the operation, according to the observations of Dr Smith. The method is being used by many Brazilian surgeons. It is not necessary to use more than 2 or 3 cc of alcohol to obtain good alcoholization.

Inter-American Congress of Surgery

The first Inter American Congress of Surgery will be held at Santiago Chile on November 14 with the cooperation of the surgical societies of Argentina Brazil, Bolivia, Paraguay, Uruguay and Chile.

The treatment of acute peritonitis will be the principal theme of the discussions. Also to be discussed are the sequels of pyogenous pleuritis of nontuberculous origin and fractures of the humerus. This congress was organized to commemorate the centenary of the University of Chile.

Immunization Against Tuberculosis

According to the data just now published by the prefecture of Rio de Janeiro there were registered in that city 33 082 births in 1941. Forty-four per cent of these children, or 14 582 were immunized against tuberculosis by BCG.

Sulfanilamide During Cesarean Section

In a recent paper read before the São Lucas Society, Dr Jose Saldanha Faria reported the results from the use of sulfanilamide during cesarean section. He pointed out the benefits of

this technic, saying a few words about intruterine sulfanilamide when a cesarean section is necessary. He advocated the use of this medicament in the practice of gynecology and in myomectomies when the enucleation may accidentally open the uterine cavity.

Marriages

- FURNIA TOWNSEND WALLACE, Chester, S C, to Miss Virginia Records of Indianapolis in Charleston, S C, August 29.
- WILLIAM HERBERT PARSONS to Mrs Victoria Blanche Gaddy both of Ellerbe, N C, in Florence, S C July 20.
- JOHN O'BRIEN WATKINS to Mrs Mary Leigh Johnstone, both of Spartansburg, S C, in New Orleans, October 2.
- DAVID E. BACSHAW, Siquinaw, Mich, to Mrs Lena Helms Britton of Atlanta Ga, in Toronto, Ont Canada, July 18.
- CHARLES E. CLONINGER, Clarendon N C, to Miss Alice Larkin of Cortopha Ala, in Washington D C, recently.
- GIVEN CLARENCE WOLF, Naperville, Ill, to Miss Marianne Simonson of Dayton Ohio, in Chicago September 30.
- CHARLES HOWARD JAMES JR Rochester, Minn to Miss Mary Jane Richolt of Holgate Ohio, September 20.
- ARCHIBALD C RANDOLPH Upperville, Va, to Mrs Theodore Aver Winthrop in Washington D C, September 3.
- EDWARD R. BARBER Cho S C to Miss Eleanor Thompson of Salem N J, at Chicope Falls Mass., recently.
- HENRY RUTHERFORD BUTLER JR, Atlanta Ga, to Miss Rhea May Ashmore at Fort Huachuca, Ariz October 9.
- JOHN MCGILL PRATT Hickory Grove, S C to Miss Dorcas Cromer at Carlisle Barracks Pa September 29.
- BEVERLY TODD TOWERY Bowling Green Ky, to Miss Jane Ethel Rborg of Nashville, Tenn, September 3.
- EDWIN MASON ROBERTSON Durlam, N C to Miss Eliza Isabelle Buckles of Bristol Va September 19.
- REX DECKER HAMMOND to Miss Barbara Tyler, both of Chicago in Little Rock Ark October 10.
- HENRY PRICE DYERIE Harrisonburg Va to Miss Mary Elizabeth Savage at Franklin August 25.
- HERBERT WILLIAM BONDIANT JR to Miss Ann Kennedy Irby, both of Atlanta Ga September 15.
- HUBERT C PATTERSON JR, Albemarle N C, to Miss Elizabeth R Fox of Philadelphia August 14.
- ALAN ESTES WALKER Waverly, Texas, to Miss Emma Murphy at Ardmore Okla August 6.
- CHARLES PETERSON MUMIN St Paul to Miss Lucia Carole Bellinger of Atlanta Ga October 1.
- IRVING I. COWAN San Diego Calif to Miss Joan Clance Rydman of Milwaukee October 30.
- FUGAT DANIEL GUYTON to Miss Eloise Butler McGill, both of Marion S C September 3.
- FRANCIS A. MARINO Springfield Ill, to Miss Margery Bond in New Orleans August 17.
- LUTHER WARREN CHILNEY to Miss Marion Margaret Moore, both of Knoxville Tenn recently.
- JOHN B. BIRCH Maywood Ill to Miss Gladys Risley of Onarga at Watseka in September.
- JOHN M. SLAUGHTER Millersville Md, to Miss Molly Powell of Florence September 7.
- ISIDORE FRILL Champaign Ill, to Miss Rosa Lee Rose in Washington D C October 13.
- JOHN E. MOSS Mobile Ala to Miss Eva Jean Williams of Charlotte N C September 9.
- THOMAS WORTH CROWELL Seattle to Miss Jean Shorkley of Carpinteria Calif, recently.
- ARTHUR DENTON JONES to Miss Mercy Lee Farris, both of Jacksonville, Fla October 4.
- RUDOLPH FENZER VOGT to Miss Catherine Clark Duffy, both of Louisville Ky recently.
- RONALD E. CORKEP Natchitoches La, to Miss Ruby Jones at Franklinton recently.
- LAWRENCE S. SIEGEL to Miss Sandra Coe, both of Los Angeles November 8.
- WILL W. STRANGE to Miss Charline Googe both of Booneville, Miss in July.
- EDWIN B. BILCHICK to Miss Ruth Coleman, both of New York, July 30.

Deaths

Rossner Enders Graham * Oakland, Calif. Tulane University of Louisiana School of Medicine New Orleans 1914, Army Medical School, Washington, D. C., 1917, specialist certified by the American Board of Psychiatry and Neurology, Inc., a first lieutenant in the medical reserve corps at Base Hospital, Fort Sam Houston, Texas, in 1916 commissioned a major in the medical corps of the U. S. Army in 1918, regimental surgeon with the 27th infantry, American Expeditionary Forces, in Siberia in 1919, chief of the neuropsychiatric service at the Letterman General Hospital, San Francisco, from 1919 to 1922, station surgeon and psychiatrist in the U. S. Disciplinary Barracks at Alcatraz in 1922, consultant at Mills College in the neuropsychiatric service of the Oakland Health Center from 1923 to 1928, served on the staffs of the Peralta, Highland and Alameda County and Providence hospitals, aged 54, died, October 6.

William John Dougherty * Brownsville, Texas, Bellevue Hospital Medical College, New York 1898, member of the Medical Society of the State of New York and of the National Gastroenterological Association, specialist certified by the American Board of Psychiatry and Neurology, Inc. also a lawyer, formerly on the surgical staff of St. Vincent's Hospital, New York, attending neurologist at the Broad Street Hospital, New York, and an assistant alienist in the psychopathic department at the Bellevue Hospital, New York, at one time on the staffs of St. John's Riverside and St. Joseph's hospitals, Yonkers, N. Y., and the U. S. Veterans Hospital, New York, in 1937 was appointed consultant psychiatrist for the Catholic Archdiocese of New York, aged 64, died, November 26, in the Mercy Hospital of chronic myocarditis.

Samuel Hanford McKee, Montreal, Que., Canada, McGill University Faculty of Medicine, Montreal 1900, specialist certified by the American Board of Ophthalmology, formerly professor of ophthalmology at his alma mater and member and past president of the American Academy of Ophthalmology and Otolaryngology, member of the American Ophthalmological Society and the Association for Research in Ophthalmology, Inc., formerly vice president of the Pan American Congress of Ophthalmology, past president and secretary of the Montreal Medico Chirurgical Society, on the staff of the Montreal Maternity Hospital from 1906 to 1914, served with the Canadian Expeditionary Forces during World War I, on the staffs of the Montreal General and Alexandra hospitals, aged 67, died, November 25.

John Harold Morris * New York, Cornell University Medical College, New York, 1914, specialist certified by the American Board of Surgery, assistant clinical professor of surgery at the New York University College of Medicine, formerly assistant professor of clinical surgery at the New York Post Graduate Medical School, Columbia University, fellow of the American College of Surgeons, served as a major overseas with the New York Post Graduate Hospital unit during World War I, visiting surgeon at the Welfare Hospital for Chronic Diseases and St. Vincent's Hospital, associate visiting surgeon, Bellevue Hospital, assistant visiting surgeon, Willard Parker Hospital, aged 53, died, November 24, in the New York Hospital.

Frank W. Cregor * Indianapolis, Medical College of Indiana, Indianapolis, 1894, retired as head of the department of dermatology and syphilology at the Indiana University School of Medicine in 1942, specialist certified by the American Board of Dermatology and Syphilology, member of the American Dermatological Association, member of the Judicial Council of the American Medical Association from 1923 to 1933 and member of the House of Delegates 1925-1926 and from 1929 to 1934, past president of the Indiana State Medical Association, formerly a member of the state board of health, at one time state senator, on the staffs of the Indianapolis City, Indiana University and Methodist hospitals, aged 69, died, Dec. 9, 1942.

George Skinner McCarty, Walla Walla, Wash. University of Maryland School of Medicine, Baltimore 1905, formerly a passed assistant surgeon in the U. S. Public Health Service Reserve and on the staff of the Veterans Hospital number 50 Whipple Barracks, Prescott, Ariz., served with the American Expeditionary Forces in France during World War I, aged 60, served as a specialist in tuberculosis on the staff of the Veterans Administration Facility, where he died, November 19, of acute glomerular nephritis due to acute prostatitis with abscess and active pulmonary tuberculosis.

Joshua Allen, Philadelphia, Hahnemann Medical College of Philadelphia, 1878, aged 91, died, November 8.

Charles Arburn, Wadesville, Ind., Kentucky School of Medicine, Louisville 1889, member of the Indiana State Medical Association, aged 84, died, November 27, of hypostatic congestion of the lungs and chronic myocarditis.

Henry Bagully, Brooklyn, Long Island College Hospital, Brooklyn 1900, member of the Medical Society of the State of New York, aged 74, died, September 25.

Stanley A. Baranowski, Milwaukee, Milwaukee Medical College, 1910, member of the State Medical Society of Wisconsin, chairman of the advisory board of the Johnston Emergency Hospital, a member of the staff of St. Luke's Hospital and a house physician at St. Joseph's Orphanage, aged 57, died, November 1, of acute cardiac dilatation and chronic myocarditis.

George H. Barbour, Helena, Mont., Medical College of Ohio, Cincinnati, 1886, member of the Medical Association of Montana, member of the state board of medical examiners from 1899 to 1906, surgeon for the American Smelting and Refining Company for forty years, aged 79, died, November 19, in St. Peter's Hospital of chronic myocarditis.

Samuel S. Barrett, Nevada, Ohio, Western Reserve University Medical Department, Cleveland, 1895, aged 80, died, November 5.

Edward M. Bench * Galena, Ill., Northwestern University Medical School, Chicago, 1898, recently served on the draft board and during World War I on the staff of the Mercy Hospital, Dubuque, Iowa, aged 70, died, November 27, of cerebral thrombosis.

William Bernard Burns, Boston, Maryland College of Eclectic Medicine and Surgery, Baltimore 1914, aged 54, died, November 15, in Mills of coronary thrombosis.

Allen Melville Carpenter, Carmel, Calif., Cooper Medical College, San Francisco, 1895, aged 72, died, November 18, in the Roosevelt Hospital, New York, of carcinoma of the colon and renal insufficiency.

James S. Cleland, Chicago, Missouri Medical College, St. Louis, 1898, aged 64, died, November 15, in the Veterans Administration Facility, Hines, of coronary heart disease and angina pectoris.

Bert Daniel Clutch, Booneville, Ark., Kansas City (Mo.) College of Medicine and Surgery, 1919, aged 61, died, November 22, of a cerebral hemorrhage.

John Moore Crump, Oakland, Calif., University of the City of New York Medical Department, New York, 1879, aged 88, died recently of congestive heart disease.

Frederick M. Eaton, Oakland, Calif., Hahnemann Medical College and Hospital of Philadelphia, 1889, aged 80, died recently of chronic myocarditis.

John Ralph Ferguson, Monroe, La., University of Nashville (Tenn.) Medical Department, 1908, aged 63, died, October 31.

Charles Webster Hamm * Troy, N. Y., Albany Medical College, 1893, past president and vice president of the Rensselaer County Medical Society, aged 73, died, October 3.

Baynard Lawton Harris, St. Charles, S. C., University of Nashville (Tenn.) Medical Department, 1897, aged 69, died, November 5.

James Harris, Lakeland, Fla., Cincinnati College of Medicine and Surgery, 1893, for two years taught pathology at his alma mater, aged 80, died, November 15, in the Morrell Memorial Hospital of senility, renal insufficiency and prostatic infection.

Cephas Cole Hill, Darlington, S. C., University of Maryland School of Medicine, Baltimore, 1904, member of the South Carolina Medical Association, past president of the Tri-County Medical Association and of the Darlington County Medical Society, for many years surgeon for the Atlantic Coast Line and Seaboard railroads, recently served as a medical examiner for the draft board and in the same capacity during World War I, aged 64, died, November 8, in the McLeod Infirmary, Florence.

Charles Addison Hurd, Northwood, Iowa, State University of Iowa College of Medicine, Iowa City 1888, member of the Iowa State Medical Society, for many years health officer, commissioner of insanity and coroner, a member of the Selective Service System during World War I, organized and for many years president of the Worth County Historical Society, aged 81, died, November 9.

Blyford B. Jackson, Lawrence, Kan., Meharry Medical College, Nashville, Tenn., 1909, aged 64, died, November 7.

Egerton Sowerby Jackson, Bronxville, N. Y., Trinity Medical College, Toronto, Ont., Canada 1888, formerly assistant attending physician at the Bellevue Hospital, New York.

and clinical assistant at the New York Hospital, New York, aged 73, died recently of hemorrhage into the cerebrum, arteriosclerosis and cerebral endarteritis

Hampar Boghoss Kazanjian, Los Angeles Baltimore Medical College, 1898 member of the Massachusetts Medical Society, aged 68, died, September 20, of cerebral hemorrhage due to arteriosclerosis

William Charles Keettel, Lyons, Neb., John A. Creighton Medical College Omaha 1901, aged 67 died November 12, in a hospital at Omaha of paralysis agitans and bronchopneumonia

Marion Luther Klinefelter * St. Louis Washington University School of Medicine, St. Louis 1903, member of the Clinical Orthopaedic Society and of the American Academy of Orthopaedic Surgeons, fellow of the American College of Surgeons, aged 69 consulting orthopaedic surgeon, Frisco Employees' Hospital, orthopaedic surgeon to the Evangelical Deaconess Home and Hospital and the Missouri Baptist Hospital, where he was shot and killed by a former patient November 28

Knute Andreas Kyvig, Poulsbo, Wash. College of Physicians and Surgeons of San Francisco 1905, aged 74, died, October 27

John William MacMullen, South Mountain Pa., College of Physicians and Surgeons, Baltimore, 1904 member of the Medical Society of the State of Pennsylvania served with the American Expeditionary Forces in France during World War I, chief of the state tuberculosis clinic at Harrisburg from 1907 to 1934, aged 63, since 1934 senior resident physician on the staff of the Pennsylvania State Sanatorium number 1, where he died, November 17 of cardiovascular disease

Jerry James McFarland, Lebanon, Tenn. Vanderbilt University School of Medicine Nashville, 1893, member of the Tennessee State Medical Association, formerly bank president, aged 71, on the staff of the McFarland Hospital where he died, November 11, of myocarditis and hypertrophy of the prostate

William Rennie McKinnon, Detroit University of Michigan Medical School, Ann Arbor 1918 aged 57 on the staff of the Highland Park (Mich.) General Hospital where he died, November 23 of cardiorenal vascular disease

Arnold Edwards Mulford, Bridgehampton N. Y. University of Georgia Medical Department Augusta 1915 aged 56, died, October 26

Deo Clifton Munger, Ellsworth, Wis., Rush Medical College, Chicago, 1888, aged 79, died October 24

Henry H. Nast, Los Angeles University of Denver Medical Department, 1897, aged 83, died November 3, of coronary thrombosis and arteriosclerosis

Norman Pearson, Pontiac Ill. Northwestern University Medical School, Chicago, 1901 aged 64 died, November 19 in a hospital at Peoria of bronchopneumonia

John Joseph Price, Olyphant, Pa., Baltimore Medical College 1896 member of the Medical Society of the State of Pennsylvania served during World War I, aged 68, died, October 28 in Wilkes-Barre

Lucien Henry Arthur Ranger, Montreal Que. Canada Laval University Faculty of Medicine Quebec 1919, served during World War I, on the staff of the Hospital Ste. Jeanne d'Arc aged 49, died, November 14

Alexander H. Redding, Cedar Falls N. C., College of Physicians and Surgeons, Baltimore, 1887, member of the Medical Society of the State of North Carolina aged 85, died, November 16, of heart disease

Henry David Reed * Pottstown Pa. Jefferson Medical College of Philadelphia, 1903, past president of the Montgomery County Medical Society, recently a member of draft board number 9, on the staff of the Pottstown Hospital aged 62, died, November 17, of coronary occlusion

Harry Campbell Reynolds * Passaic, N. J., New York Homeopathic Medical College and Hospital, New York, 1899 served in France as a major in the medical corps of the U. S. Army during World War I, fellow of the American College of Surgeons, recently became a director of the city's emergency hospital service, in charge of organizing medical and nursing units, aged 67, member of the board of governors and on the staff of the Passaic General Hospital, where he died, November 21, of pneumonia

Peter Anthony Ritchie Jr., North Little Rock, Ark. University of Arkansas School of Medicine, Little Rock, 1940 aged 27, died, November 10 in a hospital at Little Rock as the result of a fall when pushed from an automobile while trying to detain a drunken driver

John Morrow Robb, Blind River, Ont., Canada, University of Toronto Faculty of Medicine 1903, first elected to legislature of Ontario for constituency of Algoma in 1915, reelected in 1926 and in 1929, minister of health, province of Ontario, from 1930 to 1934 and minister of labor in 1934, built and equipped own private hospital at Blind River, aged 66, died, December 11

Charles Henry Robbins, Altadena, Calif., Baltimore Medical College 1895, aged 73, died, September 9, of myocarditis due to chronic nephritis

James F. Rupe, Smithville, Mo., Emsworth Medical College, St. Joseph 1886 member of the Missouri State Medical Association, aged 79, died, November 7, in the Trinity Lutheran Hospital Kansas City, of pneumonia

Charles Frederick Seafers, Palestine, Texas, Kentucky School of Medicine, Louisville 1897, served as a medical examiner on the Jefferson County draft board during World War I, formerly member of the school board of Port Arthur, superintendent of St. Mary's Hospital, Gates Memorial, Port Arthur, from 1911 to 1917, aged 70, died November 16, of coronary occlusion

Eloise Augusta Sears, Boston, Boston University School of Medicine, 1888, aged 88 died November 5

Clarence Mars Selfridge, Oakland, Calif. Hahnemann Medical College and Hospital of Philadelphia, 1887, aged 82, died September 11, of bronchopneumonia

Harsh Hyman Shiell, Los Angeles Detroit College of Medicine and Surgery, 1916 aged 53 died November 9, of a cerebral vascular stroke due to hypertensive heart disease

John Spicer, Goldsboro N. C. Bellevue Hospital Medical College New York, 1889 aged 72 died, November 15, in Winston-Salem of pulmonary thrombosis

Henry Storgaard, Seattle Chicago Hospital College of Medicine 1916 formerly assistant surgeon in the U. S. Public Health Service Reserve, assistant health officer of King County, aged 49 died November 7

Charles Mathias Tinsman, Adm. Calif., College of Physicians and Surgeons Keokuk Iowa 1898 at one time associated with the Indian Service, aged 76, died, November 6

William Arthur Trevena, Ocala, Tenn. Atlanta (Ga.) School of Medicine 1911, served as a member of the county court and of the county school board for many years, aged 61, died November 14 in the Newell and Newell Sanitarium Christman operation of intestinal obstruction following an old appendicitis operation

Harry Abram Walker * Somerville, Mass. Cornell University Medical College, New York, 1905, served during World War I, on the staff of the Somerville Hospital, aged 61, died October 30

James Edward Wallace * Biloxi Miss. Medical Department of Tulane University of Louisiana New Orleans, 1909, served as a captain in the medical corps of the U. S. Army during World War I, on the staff of the New Biloxi Hospital, aged 62, died, October 28

Harold Homer Webb * Ottumwa, Iowa, University of Maryland School of Medicine Baltimore 1912 specialist certified by the American Board of Radiology, Inc., member of the Radiological Society of North America, Inc. and the American College of Radiology, on the staffs of the Ottumwa Hospital, St. Joseph Hospital and the Sunnyslope Sanatorium, aged 52, died, November 4

DIED WHILE IN MILITARY SERVICE

Cyrus Cathey Brown * Medical Inspector Commander, U. S. Navy San Diego Calif., Johns Hopkins University School of Medicine Baltimore, 1912, U. S. Naval Medical School, Washington, D. C., 1921 entered the medical corps of the U. S. Navy Jan. 6 1921, aged 56 died, November 9 at the Naval Air Station Dutch Harbor, Alaska, of acute enteric tuberculosis and hypernephroma of the right kidney

John Richard Hatfield Orlando Fla. University of Tennessee College of Medicine Memphis, 1935 member of the Florida Medical Association, entered the Army of the United States as a first lieutenant Jan. 7, 1941 and was stationed at Fort Jackson S. C. until May 5 1942, was a major with the Johns Hopkins unit at the time of his death somewhere in the Pacific, October 22, of coronary thrombosis aged 38

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Elip—This preparation contained potassium bitartrate, sulfur and emodin according to the Federal Trade Commission, with which agency Edmond W. Caforio trading as Hempstead Selipon Company, Hempstead, N. Y., signed a stipulation in August 1942. In this Caforio agreed to discontinue the following misrepresentations: that Elip is a harmless remedy or cure for hemorrhoids or will dry them up, cause the suffering that attends hemorrhoids to cease or relieve itching, inflammation or bleeding caused by this condition. Caforio further agreed to discontinue any advertisements which did not reveal that the product should not be used when the patient suffers from stomach ache, cramps, colic, nausea, vomiting or other symptoms of appendicitis, provided however that the advertisements need contain only the statement: "Caution: Use only as directed when directions on the label include a warning to the same effect."

Giolamo Pagliano Syrup—In a stipulation signed in August 1942 with the Federal Trade Commission, the Alpinol Corporation, New York, agreed to cease making these misrepresentations for their product that it has a purifying effect on the blood or bodily humors, eliminates noxious substances, is a remedy or cure for any disease or possesses any therapeutic value except as a cathartic. Further, they agreed to discontinue any advertisements which did not clearly reveal that this syrup should not be used when abdominal pain, nausea, vomiting or other symptoms of appendicitis are present and that its frequent or continued use may result in dependence on laxatives, provided however that it would be sufficient for the advertisements to state: "Caution: Use only as directed if the directions for use on the label contain a warning to the same effect."

Isidore Rosen Distributor of Cosmetics of Various Manufacturers—Under the name of Howard Wig Company, located in New York, Rosen sells hair goods, toilet preparations and related products, some of which are mentioned below. In October 1942, Rosen stipulated with the Federal Trade Commission that he would discontinue making the following misrepresentations: that healing will be accomplished by use of Nadine Flesh Soap, that Nadivola Bleaching Cream will clear away freckles or muddy, sallow skin or is capable of whitening the skin, that High Brown Cold Cream is a skin food, that 'Overtons High Brown Bleach Ointment' is an effective treatment for pimples, blackheads, eczema or other skin diseases, that Aida Hair Pomade 'encourages the growth of hair or is a competent treatment for dandruff, that High Brown Hair Grower' will grow hair or be a competent treatment for dandruff, that Apex Hair Preparation is an effective treatment for dandruff or thin or falling hair or that Apex Pomade' is an effective treatment for short thin or falling hair, thin temples or scalp eruptions, generally. Rosen further agreed to cease representing that 'Mme. C. J. Walkers Hair Preparation', 'Mme. C. J. Walkers Tetter Salve' and 'Mme. C. J. Walkers Temple Grower' are hair growers or effective in promoting the growth of hair, that either 'Overtons High Brown Bleach Ointment' or 'New Herolin Double Strength Skin Whitener' is an effective treatment for ringworm or indicated as an application for all cases of ringworm, generally, unless in connection with such representation and in equally conspicuous type it shall be made clear that the effectiveness of such application is limited to that of temporarily affording relief from the symptoms thereof.

Klirab—This was put out by one Anna Plotz, Chicago, and consisted of an iodine salve according to the Federal Trade Commission, with which Miss Plotz signed a stipulation in August 1942. In this she agreed to cease representing that her product is a cure or competent treatment for scrofula or goiter, generally, or any kind of goiter other than the simple type resulting from iodine deficiency. She further agreed to cease making representations which attribute to her product any action on goiter, scrofula or conditions similar to them in excess of what it actually possesses.

Prunlax—In September 1942 the Adams Laboratories, Inc., St. Louis, stipulated with the Federal Trade Commission that it would discontinue these misrepresentations in its advertising that Prunlax is a remedy or cure for constipation, aids in toning up the liver or the kidneys or is effective in the treatment or prevention of backaches, headaches, biliousness, colds and swollen joints, that it renews or strengthens lost energy and keeps children full of energy, arrests colitis or the formation of

hemorrhoids or fissures or that prune juice is the basis of this preparation. The concern further stipulated that it would cease representing through the use of the brand name 'Prunlax' or with other words or pictorial representations that its product derives its laxative properties from prunes and agreed to stop using the word 'Laboratories' in connection with its business when it does not own, control or direct a laboratory where research work is conducted in connection with manufacturing this nostrum. The concern further agreed to discontinue any advertisements which represented that Prunlax is safe to use or which failed to warn that it should not be used when abdominal pain, nausea or other symptoms of appendicitis are present and that the frequent and continued use thereof may result in dependence on laxatives. It was permitted however to limit these warnings to the statement: "Caution: Use only as directed if the label contained directions for use which included this warning."

Red Hearts—That this product would restore youthful vigor or sex vitality or act as an aphrodisiac or stimulant were misrepresentations which the Reese Chemical Company, Cleveland, agreed to discontinue according to a stipulation which they signed with the Federal Trade Commission in August 1942. In March 1936 this concern was prosecuted and fined in a district federal court for violating the Pure Food and Drugs Act in selling two products, one of which was 'Red Heart Blood Tab' under false and fraudulent claims. In this connection government chemists reported that the 'Blood Tabs' were pills coated with sugar and lime carbonate and containing chiefly an iron compound, small amounts of zinc phosphide and plant extractives including nuxvomica, capsicum and an emodin bearing drug.

Speedo Headache Powders—These are a product of the Standard Sales Company, Birmingham, Ala., which concern in October 1942 stipulated with the Federal Trade Commission that it would discontinue the following misrepresentations: that these powders will have any effect on colds in excess of such relief as they may afford for the pain and discomfort of head colds; that they will eliminate remedy or cure head colds, minor muscular aches, simple neuralgia or jittery nerves; that they are a stimulant or contain special ingredients that dissolve in a hurry or that they are safe to use. The concern further agreed to discontinue any advertisements which did not clearly reveal that these powders should not be used in excess of the recommended dosage since such use might cause dependence on the drug, skin eruptions, mental derangement or collapse and that they should not be taken by or administered to children. It was provided however, that it would be sufficient for such advertisements simply to state: "Caution: Use only as directed if and when a warning to the same effect appears with the directions on the labeling."

Sphinx (Dr.) Sarsaparilla and Iron with Iodide Potash—This nostrum was the subject of a stipulation signed with the Federal Trade Commission in September 1942 by C. E. Prescott trading as Prescott Drug Company, Memphis, Tenn. In this he agreed to cease representing that his product is an effective treatment for bad blood, rheumatism, malaria, general run down condition or stomach trouble and cleanses the blood, liver and kidneys. He further agreed to cease representing by the use of the prefix 'Dr.' in the brand name that his product is made or offered for sale by a doctor of medicine and to stop using the word 'Sarsaparilla' to refer to any preparation which does not contain sarsaparilla in sufficient quantity to possess therapeutic value. Further, Prescott agreed to discontinue any advertisements which did not reveal that his preparation should not be used by persons suffering from tuberculosis or thyroid diseases or when abdominal pains, nausea or other symptoms of appendicitis are present, provided however that such advertisements need contain only the statement: "Caution: Use only as directed if the directions for use on the label contain a warning to the same effect."

Sulfo Bath—That this gives relief from nervousness, colds, insomnia, eczema, hives or poison ivy, is health giving, provides radiant health, imparts energy or has any effect on rheumatism, neuritis, sciatic arthritis or lumbago except to relieve their accompanying pains were misrepresentations to be discontinued in the advertising according to a stipulation which B. G. Pratt Company, New York, signed with the Federal Trade Commission in October 1942. This concern further agreed to cease representing that Sulfo Bath, by causing the skin to absorb sulfur, would give one a healthy or beautiful complexion or correct the conditions which cause dandruff, itching scalp, falling hair, skin troubles and severe cases of athlete's foot.

T Lax—This product was the subject of a stipulation made in September 1942 between the T. Lax Products Company, Birmingham, Ala., and the Federal Trade Commission. In this the concern agreed to cease representing that its product can be relied on to bring about or maintain good health, that it is effective in treating stomach, liver or kidney disorders, indigestion, biliousness or similar ailments, that it will act as a laxative or have any effect on the liver or act as a diuretic or aid to the kidneys or that it will remove the poisonous accumulation from the blood stream or is different from all other products sold for the same purpose. The company further stipulated that it would discontinue any advertisements which represented that T. Lax is in all cases safe or harmless or which did not warn that it should not be used when abdominal pains, nausea, vomiting or other symptoms of appendicitis are present, provided however that such advertisements need contain only the statement: "Caution: Use only as directed when the same warning appears in the directions for use on the label."

Vaseline Hair Tonic—In September 1942 the Cheesbrough Manufacturing Company, Consolidated and the McCann-Erickson Inc., advertising agency, both of New York, stipulated with the Federal Trade Commission that they would cease representing that this preparation prevents or tends to prevent the recurrence of dandruff, scales, affects the cause of dry scalp or goes to the root of that disorder.

Correspondence

THE FIRST CARDIAC CLINIC

To the Editor—On Oct 7, 1942 Mary E. Wadley died in Albany, N. Y., in the fullness of her 90 years. Her passing off the scene ought not to fail of being recorded. In the history of the development of interest in cardiac diseases Miss Wadley played an important even if not a conspicuous part. She was the first one to recognize the fact that cardiac patients were receiving less care than they deserve or than it was possible to give to them. Miss Wadley was head of the Social Service Department of the Bellevue Hospital in New York City. What she did was to create for the Bellevue Hospital Social Service a cardiac clinic for working adults. She saw the need and stimulated Dr. Hubert V. Guile to undertake the creation of the Friday evening clinic. The movement which she brought into being can most fittingly be described in her own words in a letter written by her on Feb. 9, 1938:

"It is quite true," she tells me, "that the initial move in establishing this clinic belongs to Bellevue Social Service. Scores of cardiacs discharged from the wards were referred to Social Service for convalescent care and for assistance in finding suitable employment. This we could do, but continued medical oversight was imperative if they were to carry on. For most of them this oversight was obtainable only in the day clinics, and day clinics and jobs were incompatible. The situation was most distressing to patients, to physicians and to the hospital. We social workers knew that the solution for a large proportion of cases could be found in a special evening clinic, but there was prejudice against evening clinics. Dr. Hubert Guile was deeply interested in these cases and he agreed to give his time to directing an evening clinic if the hospital authorities would consent to the innovation. They did consent to it as an experiment [A Survey of the Bellevue Experiment in Preventive Work for Cardiacs by Katharine Tyng, in *Bellevue and Allied Hospitals Social Service Reports 1910-1914* is available at the New York Academy of Medicine]. This was in 1911, and there has practically been no Friday evening at Bellevue since then without a Cardiac Clinic Session. We chose Friday for the clinic as that would give the patient a two day rest, if needed, with the loss of only half a working day, and he could be back on the job Monday morning before a new worker could replace him. Our Social Service Committee was greatly interested and contributed the salary of a full time special worker. After devoting his time for several years to this clinic, Dr. Guile felt he must retire. He had interested many young physicians in the opportunity the clinic afforded for an intensive study of heart disease. Dr. John Wyckoff had been one of the most interested assistants and he was persuaded to take Dr. Guile's place. He threw himself into the further development of the work with great zeal and was influential in the establishment of many similar evening clinics elsewhere."

In order to complete the record, it is desirable to quote the course of subsequent events:

"There is good evidence that with this account of the role played by the Social Service in this movement Wyckoff would wholeheartedly have agreed. He insisted on designating this clinic 'Bellevue Hospital Social Service Cardiac Clinic for Working Adults' for this was the title of the clinic when it was turned over to him in 1919 by Dr. Guile. In his plan of organization the Social Service was the center to which all action moved and to which all action returned. In 1925 when he described the organization of cardiac clinics to the Medical Society of the State of New York ['The first clinic in this country for ambulatory cardiacs was established in 1911 by Dr. Hubert V. Guile in Bellevue Hospital. It was begun

because the Social Service Department of the Hospital felt that the number of returns of cardiac patients to the wards could be diminished if the patients could, on discharge, be cared for in a clinic less crowded than the General Medical Clinic, and manned by physicians who would have time to become interested in the special problems of the heart patient," *New York State J. Med.* 25:996, 1925] the position of the Social Service at the center of things was conspicuously indicated. And he repeated these statements in 1929:

"The first cardiac clinic in the United States as a matter of fact was organized at Bellevue Hospital in 1911 by Dr. H. V. Guile at the request of Miss Wadley, the head of the Social Service Department, who felt the pressing need for the medical supervision of the ambulatory cardiac. In 1919 I took over this clinic, having during the preceding eight years worked in it at various times [A Consideration of Causes of Heart Disease from the Standpoint of a Social Worker, *Hosp. Social Service* 19:514, 1929]." John Wyckoff, 1881-1937, by Alfred L. Colm, *Bulletin of the Institute of the History of Medicine* 6, No. 7 (July) 1938.

One of the pitics in recording the lives of persons and the history of movements is frequently the paucity of information that is available. But in this instance by good chance the beginning is known of an important matter. The care of patients suffering from cardiac diseases moved through Miss Wadley's insight and interest, into a new era. If there were cardiac clinics at all or cardiac clinics having a purpose such as this one before the one at Bellevue Hospital it is unknown to us. And so both to record the beginning of a valuable movement as well as to commemorate the name of Mary E. Wadley, a distinguished worker in this vineyard of the Lord, it is gratifying to record this piece of history.

ALFRED L. COLM, M.D., New York

Member, Rockefeller Institute for Medical Research,
Chairman, Committee on Research

"WAR AND THE SPREAD OF EPIDEMIC DISEASES"

To the Editor—No doubt you recall your editorial entitled 'War and the Spread of Epidemic Diseases' in *THE JOURNAL*, Aug. 2, 1941, page 368. This was written in view of reports in regard to plague.

Because of certain recent positive findings of plague in rodents and their accompanying insects in Marin County, across the Bay from San Francisco, the question of reported plague was investigated. From the *Public Health Reports* of the United States Public Health Service for the last six months (April to October 1942) and the reports of the California State Board of Health, January to November 1942, plague has been demonstrated in rodents and their accompanying insects in twenty counties of California but not in San Francisco. Likewise it has been reported from the territory of Hawaii and the states of Montana, Nevada, Idaho and Oregon. Plague was demonstrated in these communities in fleas, lice and ticks and in tissue organs of ground squirrel, rat, pack rat, wood rat, brush rabbit, chipmunk and marmot.

This should demonstrate the magnitude of the problem of rodent plague, which happily is not being transmitted to human beings at the present time. The possibilities of transmission, however, from rodents and their accompanying insects in rural areas to the rodents and their accompanying insects, particularly rats and fleas in cities has many dangerous angles.

EPIDEMIC KERATOCONJUNCTIVITIS

To the Editor —Among some of the growing problems which have confronted both health officers and industrial physicians in the country during the past year has been that of epidemic keratoconjunctivitis, called by some "shipyard conjunctivitis." The disease is apparently new to this country, but it has appeared in epidemic form both on the West Coast and in the East (and perhaps elsewhere) during the short space of a few months. During this period, however, much has been learned, to which recent articles testify (Hogan, M. J., and Crawford, J. W. Epidemic Keratoconjunctivitis, *War Med* 2 984 [Nov] 1942; Sanders, Murray. Epidemic Keratoconjunctivitis, *Arch Ophth* 28 581 [Oct] 1942; Isolation of a Virus of Epidemic Keratoconjunctivitis, Current Comment, *THE JOURNAL*, Oct 17, 1942, p 538). This information is not general as yet and apparently epidemic situations can develop insidiously in factories before the nature of the conjunctivitis in its potential seriousness is recognized.

To my knowledge the disease is not reportable in this country, and because of this and other obvious reasons it seems wise to bring it to the attention of *THE JOURNAL*. It is earnestly requested that if new outbreaks, or suspected outbreaks, of this disease (epidemic keratoconjunctivitis) should occur, notification of this fact be made to Dr. Murray Sanders (Department of Bacteriology, College of Physicians and Surgeons 630 West 168th Street, New York City).

Dr. Sanders has been assigned by the Board for the Investigation of Epidemic Diseases in the U. S. Army to study this problem and to assist in the control of this disease.

THE RETAN TECHNIC OF
SPINAL DRAINAGE

To the Editor —The editorial on forced spinal drainage in acute poliomyelitis in *THE JOURNAL*, September 26, should be corrected in the part describing my technic. Your description is erroneous. It begins with the statement "Since then the suggested technic has been simplified by Retan, who reported equally beneficial effects on omitting the accompanying lumbar or cistern puncture." The treatment period is of five hours instead of eight. The suggested rate of injection of the hypotonic salt solution is 10 cc per pound hourly, never giving over a liter an hour and reducing the rate of injection during the last two hours of treatment, also decreasing the rate of injection if the blood pressure rises. Free drainage of cerebrospinal fluid is never allowed for fear of cerebellar herniation. The technic in relation to drainage of cerebrospinal fluid follows: At one half hour intervals the nurse in charge of the case should remove the stylet from the needle and allow 5 cc of cerebrospinal fluid to drain if the fluid flows from the needle in a stream, if it flows in a rapid drop, she is to remove 2 cc, if in a slow drop she is to replace the stylet in the needle without removing any fluid. It has been shown that the drainage of cerebrospinal fluid is not related to the therapeutic result. These small amounts of cerebrospinal fluid are removed to prevent possible increase in intracranial pressure.

MEDICOLEGAL ABSTRACTS

Autopsies Right of Employer's Insurance Carrier to Require Autopsy on Body of Employee—Simphins had been employed by the Jones Construction Company, but prior to actually assuming the duties of employment he died of a heart attack. Following the death, the defendant, the insurance carrier of the employer, with the permission of the industrial commission of South Carolina, had an autopsy performed on the body. Subsequently the plaintiff, the deceased's wife, sued the insurance carrier to recover damages for the performance of the autopsy. She alleged that she had neither filed nor intended to file a claim under the workmen's compensation act and that the autopsy was performed against her will and with no notice to her or any hearing whatever. The defendant demurred on two grounds: (1) that the plaintiff was not the proper party to maintain the suit, and (2) that the autopsy was authorized by the workmen's compensation act of South Carolina. The trial court overruled the first ground of demurrer but sustained the second ground and the plaintiff appealed to the Supreme Court of South Carolina. The Supreme Court adopted in toto the opinion of the trial court, and it was published as the opinion of the Supreme Court.

With respect to the first ground of demurrer the trial court held that in the absence of testamentary disposition, the surviving spouse if living with the decedent at the time of death is the proper party to maintain an action based on the mutilation of a corpse. If there is no surviving spouse the court said, then the next of kin would be the proper party to maintain such a suit. But here the plaintiff, being the surviving wife of the deceased, is the proper person to maintain the action, and the first ground of demurrer interposed by the defendant was overruled.

As to the second ground of demurrer the widow argued first that the fact that the deceased had not actually commenced work under his contract of employment precluded the application to this case of section 27 of the workmen's compensation act which provides that the employer or the industrial commission, shall have the right in the case of death to require an autopsy. The court concluded, however, that that provision was applicable and that the mere fact of a hiring or of a contract for employment makes it applicable even though there had been no assumption of the duties of employment by the employee. The widow next argued in effect, that the workmen's compensation act was inapplicable as granting authority for an autopsy because she had neither filed any claim under the act nor intended to file any. The act, however, said the court, does not require an employer to wait until the claimant has filed with the commission a written claim for compensation before making his demand for a physical examination of the claimant. Such requirement would defeat the purpose of such examination. The employer is entitled to know the condition of the claimant at the time of the injury. He may take steps to minimize the effects of the

injury and thus reduce his liability. To say that the claimant may delay the physical examination for so long a time after the injury as he wishes is to put it in his power to defeat the benefit to the employer of such examination. Accordingly, continued the court, the filing of a claim or the indication of the filing of a claim has no bearing on the operation of the act. The widow then argued that the autopsy was performed at the instance of the insurance carrier rather than of the employer. In answer the court pointed out that an insurer certainly stands in the shoes of its insured employer, having his rights and being subject to his obligations.

The widow contended that since the deceased died as the result of a heart attack, not as the result of an industrial accident the right to an autopsy conferred by the act on the employer or on the industrial commission did not apply. We cannot, said the court, impose the restriction on the act contended for. The language of the act is plain and unambiguous. The act confers the right to an autopsy "in any case of death" of an employee. There is no specification as to the nature of the deaths to which the autopsy right applies. It was undoubtedly realized in the enactment of this law that there are and always will be deaths to employees which present a borderline between accidental and natural origins.

In the complaint the widow alleged that she had objected to and refused to consent to the autopsy, that she was not given an opportunity to be heard by any judicial or quasi-judicial body, that there was no hearing by such body or as required by law, and that the autopsy was had by a request, without notice to her, to the secretary of the industrial commission, without a hearing before the commission or an order of the commission therefor. These facts, she claimed, indicated a high-handed illegal and unlawful autopsy in violation of her rights. But said the court the provision in question provides:

The employer shall have the right to require an autopsy. It does not state "may", it does not qualify, it is unequivocally mandatory. There are no provisions relating to notice consent or objections. The statute specifically provides that the employer, or the Industrial Commission, shall have the right to require the autopsy. There is no ambiguity. We are not at liberty to insert any requirements as to consent or notice regardless of whether or not we think such requirements advisable. Accordingly the court held, in effect, that because of the provisions of the workmen's compensation act the insurer had a right to require an autopsy and that an autopsy so performed was not in contravention to any rights of the widow. The judgment in favor of the insurance company was affirmed.—*Simphins v. Lumbermens Mutual Casualty Co.*, 20 S E (2d) 733 (S C 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1912 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Fibromyomas of Uterus.—Of the 1,741 fibromyomas that Torpin and his colleagues report on, 575 were in white and 1,166 in Negro women from 17 to 76 years of age. In the majority of the patients the tumors were multiple. In 301 white women the tumors were smaller than 5 cm in diameter and 197 had tumors larger than 5 cm, 302 Negro women had tumors smaller than 5 cm while in 586 they were larger. Not only were the Negro women affected three and one third times as often as white women, but they also had one and a half times the incidence of the larger tumors. As regards pelvic infection, 93 of the 575 white women had salpingitis, while it was present in 633 Negro women, that is in 54 per cent of the 1,166. Forty per cent of all patients operated on for chronic salpingitis had fibromyomas. In the 575 white women 67 follicular and 43 luteal cysts were found, among the Negro women there were 225 follicular and 117 luteal cysts. Adenomyosis occurred in 21 white and in 18 Negro women. Necrosis was found in 45 white and in 190 Negro women. The incidence of necrosis was not greater in the earlier reports when operations were deferred longer than in recent years. Likewise calcification was more frequent in the Negro women. Pure myomas were found in 11 white and in 37 Negro patients. In addition to the follicular and corpus luteum cysts there were 11 cystadenomas in the white patients, in 3 they were malignant. Twelve such cysts, 5 of which were malignant occurred in the Negro women. Dermoid cysts of the ovaries occurred in nearly 1 per cent of the white patients (5 cases) and in 2½ per cent of the

Negro women (26 cases). A comparison of the endometrial changes in 100 fibromyomatous uteri and in 100 nonfibromyomatous uteri revealed that 20 per cent of the fibromyomatous uteri in white women and 10 per cent of those in Negro women were hyperplastic. For the nonfibromyomatous uteri (removed for chronic salpingitis or for bleeding late in the reproductive life associated with chronic cervicitis) the respective figures were about 15 and 20 per cent. This definitely indicates that there is no special association of endometrial hyperplasia with fibromyomas.

Changes in Female Genital Tract.—The changes in three groups of 12 patients (normal postpartum puerperas, normal postpartum women given 10 mg of diethylstilbestrol for twelve days and normal postpartum women given 10 mg of methyl testosterone for twelve days) were studied by Rutherford by endometrial biopsy and vaginal smear. The endometria and vaginal smears of the patients treated with the synthetic preparations demonstrated definite variations from the normal processes of involution repair and regeneration. Involution was delayed by the diethylstilbestrol but not by methyl testosterone, but repair was hastened by the one and definitely retarded by the other. Regeneration, that is, covering of the surface epithelium, was hastened by the diethylstilbestrol but stromal regeneration was delayed. The methyl testosterone delayed regeneration. The effects of diethylstilbestrol were no longer present after one week and the effects of methyl testosterone three weeks after their withdrawal.

Spontaneous Abortion.—Mason discusses the nineteen abortions that occurred among three hundred and eleven consecutive pregnancies cared for by him in private practice. Six of the abortions occurred in 2 patients, who had three each. This incidence of 6 per cent is considerably less than is generally reported. All the women were in comfortable circumstances, usually reported early for antepartum care, had adequate diets and received thyroid or iodine if it was indicated by a basal metabolism test or the history, and foci of infection were cared for as soon as possible. If 50 to 80 per cent of abortions are pathologic and if the chief cause is defective germ plasm, somatic factors should play no part. However, if the maternal environment is a major etiologic factor a comfortable life and preventive treatment ought to make considerable difference. The low abortion rate in the present series, together with an apparent considerable success in the treatment of abortion in these women, would seem to lend confirmatory evidence to the latter view. Among the series of pregnancies, thirty-four 'threatened' abortions were treated. In 30, or 82 per cent, the abortion did not occur and the patients were carried to term. Four aborted in spite of treatment, but 1 of these went to term in her next pregnancy, prophylactic treatment was begun shortly after the first missed menstrual period. The other 3 of the 4 were lost sight of. In addition there were 17 patients who were treated prophylactically from the beginning of their pregnancies. These patients gave a history of having had one to three previous consecutive abortions. Of these 17 patients, 15 were carried to term the first time such prophylactic treatment was given. All gave birth to normal babies, who continued to develop normally thereafter. The two failures are represented by the 2 patients who figured in six of the total nineteen abortions. In addition to all other measures which constitute good antepartum care the only other agent used in the treatment was progesterone (proluton). Morphine was not used. The progesterone was given in 5 mg doses (intramuscularly in oil) to patients with threatened abortion. If the symptoms were slight, this dose was given once a day, but, if the symptoms were more severe, 5 mg was given twice a day for several days. When cramps and/or bleeding ceased the progesterone was not discontinued immediately, but the 5 mg dose was usually given every other day for several days. The dose was then reduced to 2 mg and continued for a week or more, then the intervals were lengthened and the injections were continued for perhaps two more weeks. Patients with a history of recurrent abortion were given progesterone therapy as soon as pregnancy was diagnosed. The patient with a history of two previous abortions and no successful pregnancy should be treated through the seventh month of pregnancy.

*Patella Cubiti Report of Four Cases J E Habbe Milwaukee—p 513
Problem of Tubal Sphincter and of Intramural Portion of Fallopian Tube P Schneider New York—p 527

Roentgen Therapy of Pituitary Adenoma—Kerr and Cooper have observed 25 patients from a year to ten years or until death after they were given roentgen therapy for their pituitary adenoma. The results in 14 of the 25 are considered excellent, good in 5 and poor in 6. Twenty two of the 25 were given irradiation alone and 2 who first received roentgen therapy and failed to benefit were later found to have cystic tumors. The poor response of these 2 demonstrates the inadequacy of roentgen therapy for this type of tumor. The chief criteria for judging progression or regression of the disease are the visual field changes and loss of headache. Success or failure must be judged not on survival but on preservation or restoration of vision and the general well being of the patient. Irradiation appears to do this, especially if relatively heavy doses are employed. However, if the disease progresses during three to four months after roentgen therapy, surgical exploration should be carried out because the tumor is likely to be cystic. The relatively large doses employed by the authors resulted in untoward effects only once. The patient had arteriosclerosis and hypertension, and mental deterioration developed. These changes they attribute to the effects of irradiation on arterio-sclerotic cerebral vessels associated with hypertension.

Patella Cubiti—Habbe reports 4 cases of patella cubiti each of which occurred as a unilateral abnormality. In the third case trauma was the chief if not the only etiologic factor, the abnormality, in a patient aged 15, was found about five weeks after trauma. This condition was followed for six months, when a relatively mature state of patella cubiti was present. In the first case there was a definite history of trauma to the right elbow when the patient was 14, the only recalled diagnosis was that of 'fracture'. It was supposed that an avulsion of the olecranon epiphysis occurred together with periosteal stripping on the proximal diaphysis of the shaft by the mechanism of muscle pull, which was then followed by closure of the epiphysis and new bone formation along the distal projection. The minor trauma which occurred at 22 brought the patella cubiti to light and had no bearing on the development of the bony abnormality and apparently none on the immediate or subsequent functional status of the elbow joint. The second and fourth cases are similar as regards the history of a childhood trauma occurring at or about the time the olecranon epiphysis begins to ossify. However, the fourth patient had a relatively satisfactory clinical recovery without benefit of examination or treatment. While an etiologic relationship between childhood trauma and the formation of the patella was obtainable there may still be some doubt as to trauma being the only etiologic factor. The similarity of the so called epiphysitis in other regions, from the standpoint both of normal growth of these secondary epiphyses and of their roentgen appearance in the presence of a growth disturbance, is emphasized. In true patella cubiti any traumatic factor to be significant in the development of the condition must occur in childhood or adolescence. Hence trauma occurring in an adult employee who shows such an abnormality is not a causative factor in its appearance and the misinterpretation of fracture or 'pathologic fracture' should not be made.

Retinopathy in Juvenile Diabetes—Bloch reports 2 cases of retinal changes in juvenile diabetes in which there was no renal pathologic change or abnormal blood pressure. A number of cases in the literature suggest that diabetes itself may produce the disease known as diabetic retinitis or diabetic retinopathy. The author believes that the controversial question as to whether diabetic retinopathy proper or the retinal changes are secondary to hypertension or arteriosclerosis can be decided on the following three bases. Clinical observation will show that there is a difference between the icteric changes in the fundus in diabetes in arteriosclerosis and in hypertension especially with reference to the optic nerve and the macular region. Study at necropsy of the pathologic changes in eyes from persons known to have had diabetes may reveal that the retinal changes developed independently (koyunluk). Also information will be obtained from study of the retinal changes in diabetic persons especially young patients whose renal and blood vascular systems are normal. Many of the previous case reports are valueless because description is lacking.

Death from Foreign Protein—Vance and Strassmann found in the office of the chief medical examiner of the city of New York reports of 7 instances of sudden death following injection of foreign protein. They have correlated these cases with 19 similar cases reported in the literature in which necropsies were also made. Five of the seven sudden deaths were of persons presumably nonasthmatic. They died after injections of antivenom. The other 2 were known to have bronchial asthma; they died after injections of foreign protein. At

necropsy there were pronounced inflation of the lungs and signs of asphyxia due to bronchial spasm in all the patients. The brain of 2 was edematous and under compression. In 2 there was edema of the submucous layer of the upper portion of the trachea. Microscopic study of 6 demonstrated varying numbers of eosinophilic leukocytes in the bronchial wall, suggesting that the reactions were hypersensitive in nature. Of the 19 patients who were the subjects of the reports in the literature 13 were presumably nonasthmatic and 6 were known to have asthma. Six of the 18 nonasthmatic patients had received injections of antivenom or some other foreign protein from six to fourteen days to a number of years prior to the one causing death. The remaining 12 had received only the one injection. The product injected immediately preceding the onset of the fatal symptoms was some derivative of horse serum in 17 and a typhoid vaccine in 1. It appeared that the greater the amount of protein administered the more rapid was the fatal reaction. Ten patients, 7 of whom were children, had difficulty in breathing soon after the injection and died within ten minutes. Death was due to asphyxia caused by muscular spasm of the smaller bronchi. The death of 4 occurred in twenty to seventy minutes; the symptoms began soon after the injection or after twenty to thirty minutes. The symptoms were asthmatic in type, and the lungs at necropsy were inflated. Four patients lived for several hours after the fatal injection of horse serum. Four of the 8 asthmatic patients received horse serum derivatives, 2 pollen extract, 1 a mixture of silkworm, sheep's wool and kapok and 1 guinea pig serum. Six of these patients had not received any previous injections of protein and 2 had had regular injections of pollen extract. The symptoms at the time of death were typical of an asthmatic attack and at necropsy the lungs were inflated. The duration of the clinical course in these 8 cases varied from five to forty five minutes.

Prevalence of Sporotrichosis—Weise reports his third case of sporotrichosis, the fourth to occur in Connecticut. The disease may be mistaken for syphilis, as the ulceronodular and gummatous lesions may bear a close similarity to cutaneous gummas. Certain types of cutaneous tuberculosis and, at times, low grade streptococcal lymphangitis may be imitated. The general practitioner should consider it as a possible diagnosis in obscure ulcerative ulceronodular and gummatous conditions particularly when the lymph nodes appear to be involved. Cultures from areas which have broken through the skin either will not reveal the fungus or they will be grossly contaminated with staphylococci and other organisms. Pure cultures can almost invariably be obtained by utilizing previously unopened lesions. The 3 other culturally proved cases of sporotrichosis which have occurred in Connecticut are reviewed. The physician should familiarize himself with the various manifestations of the disease so that its true incidence may be ascertained and its otherwise prolonged period of disability avoided by appropriate management.

Treatment of Hereditary Glaucoma—Ackerman and Allen diagnosed hereditary glaucoma in 6 of 14 descendants of the originally affected member representing three generations. The average age at onset of all 7 affected members was 11.6 years with a span from 7 to 15 years. There was no tendency to anticipation. There was difficulty in controlling the condition with miotics and surgery. A single goniotomy was effective in controlling the tension in four eyes. Two goniotomies were required to control the tension in three eyes, and in an eighth eye an iridencleisis was finally required to control the tension after five goniotomies, two cyclodialyses and a deep root iridectomy failed. From the results in the 7 cases it appeared that although miotics by themselves were relatively ineffective in controlling the tension before surgery they may aid to maintain the lowered tension following surgery. The finding of glaucoma at an early age is an indication to search for a tendency to glaucoma in every other member of the family so that it can be treated before much vision is lost.

Erythrocytes and Hemoglobin Values and Acclimatization to Discontinuous Anoxia—Aviators are subjected to discontinuous anoxia, as they spend but relatively short periods aloft. Stickney and Van Lierc tried to determine in dogs how long it would take for distinctive signs of acclimatization to develop in an animal subjected to a given degree of anoxia for a certain period each day. The dogs were placed daily (except on Sunday) in a low pressure chamber in which various altitudes were simulated. Hemoglobin and erythrocyte determinations were usually made every week. At or after the third week the hemoglobin values rose, subsequently rising more or less uniformly until discontinuous exposure to anoxia was terminated. A distinct increase in the erythrocyte count did not occur before the fifth week, and thereafter it was practically uniform throughout the six months of discontinuous anoxia. Following the period of the anoxia the hemoglobin and erythrocyte values

decreased uniformly to the original values in about eight to nine weeks, respectively. The original levels were attained as though there had been no overshooting of the mark. The plotting of the color index shows that the hemoglobin values tended to increase faster than the erythrocyte values until exposure to the simulated 18,000 feet had well begun, when there was a greater gain in erythrocytes. This was indicated by the reduction in the color index. This reversal was fairly constant throughout the rest of the anoxia period, and before the values returned to normal the color index tended to be even lower before it finally regained its initial value. The erythrocyte count was increased 84 per cent by the end of the sixteenth week after exposure to a simulated altitude of 18,000 feet. Acclimatization apparently does follow discontinuous exposure to anoxia, the degree being directly proportionate to the severity of the anoxia and the length of exposure.

Wounds of Modern Warfare—MacIntosh declares that for the wounds of modern mobile warfare it is of the greatest importance to evacuate the wounded by air or, failing this, to bring early surgery to the patient, that is, mobile medical units. The closed plaster treatment permits safe transportation over long distances without the necessity of changing dressings. Patients who had debridement and plaster fixation travel well and look fit on arrival. Furthermore, continued closed plaster treatment at the base hospital seems to be the method of choice. In Canadian hospitals the method is to be adopted as routine treatment. Experience in England and in Libya shows that war wounds should not be sutured. Sulfanilamide as a prophylactic measure is not sufficient to prevent gas gangrene and other infection in the contaminated wound. The author knows of no prophylactic against gas forming organisms other than early removal of devitalized muscle. With debridement and local chemotherapy he has not seen increased healing or lessening of infection as compared to similar surgical treatment without chemotherapy. On the other hand, sulfonamides given by mouth after injury may decrease the incidence of severe streptococcal infection, particularly when there is delay in reaching an organized operating center. The application of sulfonamides to superficial wounds, particularly burns, is of undoubted value, but their routine use in deep penetrating wounds does not lessen the urgency for surgical treatment.

Sodium-Beta-Glycerol-Phosphate for Healing Fracture—Sperling and his associates investigated the effect of intravenous injections of sodium beta-glycerol phosphate on the rate that fresh experimental fractures in rabbits healed. Twenty-seven animals received six to fourteen daily injections, by ear vein, of 0.1 Gm of the drug in 4 cc of solution. Twenty-two control animals with similar fractures were given injections of isotonic solution of sodium chloride. All rabbits were killed the day following the last injection. Roentgenograms of the limbs were taken before and after soft tissue was removed from them; they revealed an increase in callus about the fracture site.

in the group treated with sodium-beta glycerol-phosphate. Also the callus was more firm to palpation than that of the control animals. Healing appeared to have progressed further than in the control animals, the callus was larger, the fracture defect was more nearly bridged over and much more callus was adherent to the periosteum.

Immersion Foot—Webster and his associates have observed 142 cases of "immersion foot," a condition produced by long immersion of the feet in cold water. As the condition may occur in feet exposed for long periods in subarctic waters, it cannot be classed as true frostbite. Almost all of the cases were the result of enemy action in the North Atlantic. The feet when the patients were removed from the open lifeboats or rafts on which they had been for varying periods were cold, swollen and very white, with scattered ecchymotic areas. The patients complained that their feet felt heavy "woody" and numb. The feet were anesthetic to pain, touch and temperature. Soon after the patients were removed from their craft the swelling increased rapidly, the feet became red, hyperemic and hot without sweating, and the pulse in the vessels of the feet was full and bounding. The initial anesthesia and hypothermia were replaced by intense paresthesia on the eighth to the tenth day after removal from the traumatizing agent. A trial of treating the feet by dry refrigeration was made at Camp Hill Hospital, Halifax, N. S. With the feet elevated, dry cooling and refrigeration were achieved by the application of ice bags (changed every four hours), dry cooling by exposure to a fan and dry cooling at room temperature. A few hours after the ice bags were applied the patients were completely comfortable, the edema subsided and blebs filled with straw-colored fluid and those filled with extravasated blood were resorbed without breaking. The blebs refilled if cooling was discontinued prematurely. The 127 patients with minimal, mild and moderate involvement, with 1 exception recovered completely after superficial desquamation over the entire foot and recalculation necessitated by an abnormal gait. Their average hospital stay was thirty and four-tenths days. Of the 15 patients with severe involvement 7 have been discharged after the loss of small areas of superficial tissue which healed rapidly and did not require grafting. Of the 8 still confined to the hospital, 5 have gross tissue defects across the mid dorsum of both feet, in 2 the superficial skin over the distal aspect of both feet has become mummified but is being shed and replaced by healthy tissue with epithelial islands throughout and in 1, to whose feet ice bags were applied for four weeks, the tissues of the feet had a healthy pink color, but in eight hours at room temperature a large quantity of blood was extravasated into the subcutaneous tissues. The feet became greenish gray, and a sharp line of demarcation between healthy and damaged tissue encircled the midtarsal region of both feet and tissue breakdown occurred. This will probably progress ultimately to extensive tissue loss over the distal aspect of both feet. The rationale of the treatment rested on the presumption that if the metabolic demands of the part could be reduced until the edema subsided, the extravasated blood resorbed and the vasomotor tone reestablished the tissue damage would be greatly ameliorated. Strict asepsis is essential because if infection develops in the damaged tissue the process spreads rapidly through all layers of the feet.

Treatment Resistant Syphilis—Beerman and Severac began in 1932 to investigate the problem of treatment resistant syphilis in rabbits. The resistant strain of *Treponema pallidum* was isolated from a patient whose primary and secondary lesions remained uninfluenced by a total of 5.4 Gm of various arsenicals but whose infection was later satisfactorily controlled by the prolonged use of bismuth salts intramuscularly and intramuscular injections of boiled milk. At first, takes in rabbits with this strain were difficult to obtain, but this decreased as the number of transfers increased, and from the sixteenth to the fifty-seventh annual passage practically every inoculated rabbit became infected. The incubation period, which was variable at first, finally averaged about four weeks. The response of this strain to arsphenamine was controlled by using the Nichols-Hough strain of *Treponema pallidum* in other rabbits and by using a standard lot of the drug, the minimal sterilizing dose of which has been 14 mg per kilogram of body weight. Thirteen of 51 rabbits treated with 14 to 30 mg of arsphenamine per kilogram of body weight failed to be "cured." This refractoriness was sporadic, it was more pronounced in the beginning of the study and occurred less frequently as the strain became adapted to the new host.

Heart Disease and Hepatic Function—The relationship of hepatic function to heart disease, as revealed by the bromsulphalein retention test and by the measurement of the velocity of the blood flow and the venous pressure, was determined by Bernstein and his associates in 29 men and 30 women aged from 19 to 79 years. Fifteen sets of determinations were performed on 15 noncardiac patients, in 14 the bromsulphalein hepatic function test was normal, while 1 had an abnormal bromsulphalein retention without a demonstrable cause. Twelve of thirteen demonstrations in 10 patients with fully compensated heart disease showed agreement and one disagreement between the cardiac status and the hepatic function. In eleven of thirteen determinations on 10 patients with mild cardiac compensation there was agreement and in three disagree-

fourteen determinations made on 14 patients, six showed the cardiac status and the hepatic function tests to be in agreement and eight showed disagreement. In 13 patients with decided cardiac decompensation eleven of fourteen determinations showed agreement between the cardiac status and hepatic function and three showed disagreement. The results indicate that the bromsulphalein excretion is normal in the absence of heart failure, in mild degrees of cardiac failure the impairment in bromsulphalein excretion is in close parallelism with the status of the circulation, in definite pulmonary congestion the correlation of hepatic function with the circulation is frequently paradoxical and in severe cardiac failure bromsulphalein excretion is usually impaired. Although there was a tendency to parallelism between the bromsulphalein excretion and the degree of cardiac failure, the authors could not determine any mathematical correlation between the two factors.

Guanidine and Muscular Dystrophy—MacFate studied the effects in guinea pigs of simple guanidine salts on creatine metabolism. The daily administration for several weeks of one third to four fifths of a minimal lethal dose of a toxic guanidine salt produced metabolic and muscular structural changes similar to those found in nutritional muscular dystrophy and in progressive muscular dystrophy. A loss of creatine and phosphate from the muscle and severe disturbances in carbohydrate metabolism and the electrolyte balance occurred. It is suggested that guanidine may lower the permeability of the muscle cell producing these changes. However 1 mg. of aminoacetic acid per gram of body weight, administered daily appeared to afford some protection against the small daily doses of the toxic guanidine salt. Aminoacetic acid seems to delay the progress of a nutritional muscular dystrophy. The abnormal metabolism of guanidine compounds may be an etiologic factor in the production of a progressive muscular dystrophy.

Enterobiasis in Children—To save time in preparing the NIH swabs and cleaning the used glass rods and also to supply an adhesive surface to which *Enterobius vermicularis* is more likely to adhere, Jacobs decided to use Scotch cellulose tape. The only materials needed for the technique are a roll of tape, wooden tongue blades and glass microscopic slides. A piece of the tape about the length of the slide is folded over one end of a tongue blade with the nonadhesive surface of the tape against the tongue blade. The ends of the tape can be held in place by the examiner's finger. This is used as an applicator and applied to the perianal folds, the pinworm eggs are picked up

by the sticky surface of the tape, which is then removed from the tongue blade and spread out, adhesive surface down, on the slide and examined directly under the low power of the microscope without the use of a coverslip. The slides can be placed in a slide box and examined at one's convenience, they may be kept for many days without any change in the appearance of the ova. In positive cases at least one of the eggs should be examined under high power. The technique was used for the diagnosis of possible enterobiasis in 228 unselected clinic children, and pinworm eggs were found in 31.3 per cent. Of the infected patients, 41.3 per cent had repeated abdominal pains, 49.4 per cent were nervous, 41.4 per cent were underweight, 38.6 per cent were poor sleepers, 38.6 per cent had anorexia, 21.3 per cent had pruritus ani and 17.3 per cent had emesis. Of the 40 infected girls, 27.5 per cent had a vaginal discharge. During the study 14 girls were seen in the clinic with vaginal discharge and 11 of them had oxyuris ovi in both perianal and vulvar regions.

Streptococcus Viridans Endarteritis—During the present year Touroff has operated (ductal ligation or division) on 4 additional patients suffering from a relatively early Streptococcus viridans endarteritis superimposed on patent ductus arteriosus. Chemotherapy was given each patient prior to operation. It did not sterilize the blood stream. The operation was ductal ligation in 3 and ductal division in 1. Following operation 3 patients received no chemotherapy and 1 received 10 Gm. of sulphyridine (on the twelfth postoperative day) because of continuing fever of obscure etiology. However, six postoperative blood cultures had already been reported negative before the drug was given. The 4 patients have recovered and have remained free from infection since operation. Among the author's 8 patients (4 in a previous series) 5 were cured, 2 died from accidental hemorrhage and the fact that 1 patient was not cured is ascribable to the presence of vegetation on the aortic valve at the time of operation. Thus among the 6 who survived 5 were cured. Ductal ligation or division is most likely to be attended with a low morbidity and mortality and a high incidence of cure if it is performed during the early stages of the infection. Since this article was prepared for publication the author has operated on 2 more patients, who recovered.

Experimental Pulmonary Edema—Recently the Gibbons and Kraul observed 2 patients who died within twelve hours of a bilateral lobectomy. Necropsies were performed on both patients, and the only significant finding was edema of the remaining lobes. To determine whether the fluids administered during and after operation were in any way responsible for the pulmonary edema, the authors performed experiments on anesthetized cats. A blood transfusion of 15 cc. per kilogram of body weight was given to 6 normal cats at a constant rate over a period of half an hour. The saturation of the arterial blood with oxygen was normal before and after the transfusion, and at necropsy no pulmonary edema was evinced. In 9 animals after lobectomy a blood transfusion of 15 cc. per kilogram of body weight was given. Most of the animals exhibited varying

degrees of insaturation of the arterial blood with oxygen, and 4 of them died shortly after the transfusion was completed. The oxygen capacity of the blood was determined in 14 cats, in 11 it was increased after all the lower lobes and the right middle lobe were removed. In 2 of the 3 remaining cats with no increased capacity subsequent blood transfusion failed to produce evidence of anoxemia and in 1 a mild anoxemia appeared some time after transfusion. They conclude that a blood transfusion of a size well tolerated by normal animals may produce pulmonary edema, a decreased saturation of the arterial blood with oxygen and death.

Clinical Perinephritis and Blood Pressure—Braasch and Wood studied the records of 70 cases of perinephric abscess observed at the Mayo Clinic in the past eleven years in order to determine its effect on blood pressure. Analysis revealed that 6 patients could be classed as hypertensive because of a systolic pressure above 145 mm and a diastolic pressure above 90 mm. This is an incidence of 8.6 per cent. In 2 of the 6 conclusive evidence was present that hypertension had existed prior to the onset of the perirenal disease. In a third patient other factors apparently were operating to influence the arterial blood pressure. Thus only 3 patients remain in whom association between perinephritis and an elevated arterial blood pressure might be present, an incidence of 4.3 per cent, which is less than half of the incidence of hypertension in a random sample of patients less than 50 years of age who register at the Mayo Clinic. In the authors' opinion this is so low that it should be relegated to chance.

Successful Treatment of Inguinal Granuloma—The various standardized methods of treating inguinal granuloma are evaluated by Tomskey and his co workers, who present a new mode of therapy. Complete cures were obtained by 102 patients who were treated with the local application of a mixture of 20 per cent resin of podophyllum in olive oil. The mode of action of the medication awaits further investigation, but the authors believe that the drug acts as a dehydrating agent on the infected granulating tissues and that it also exerts a cauterizing effect. Other active venereal infections (syphilis, venereal lymphopathia and chaneroid) were found in 55 of the patients. The patients were previously treated by various accepted methods but no cures were obtained with antimony and potassium tartrate or a combination of antimony and potassium tartrate and surgery even after from two months to almost two years of treatment and hospitalization. Patients irrespective of the type or the extent of their lesions, treated with resin of podophyllum needed considerably less hospitalization and when discharged were completely healed and have remained so. After healing, no induration, fibrosis or keloid formations were present and the skin was often soft and of normal consistency. The patients treated with resin of podophyllum were also given

antimony and potassium tartrate. Several patients were cured with resin of podophyllum alone. Not only was the average hospital stay for those patients who received resin of podophyllum about 35 per cent less but also the favorable response was more than twice that of those who were also treated with antimony and potassium tartrate. In treatment, secondary infection should be eliminated by cleansing the lesion with hydrogen peroxide and hot sitz baths twice a day. The 20 per cent resin of podophyllum in olive oil is applied to the lesion after each bath for five to seven days. Local topical analgesics are recommended for any resultant burning or pain, applied about ten minutes before the resin of podophyllum. When the exuberant granulations have disappeared and a healthy base is evident, resin of podophyllum is discontinued and scarlet red ointment is applied following each bath to stimulate epithelization. The application of resin of podophyllum to any small resistant areas should be continued if a complete cure is to be obtained.

Theory and Application of Serum "Acid" Phosphatase—Sullivan and the Gutmans give additional data on the use of the serum "acid" phosphatase activity as an aid in the diagnosis of metastasizing prostatic carcinoma. They base their remarks on the results obtained on 200 patients with prostate carcinoma, on 33 of whom castration was performed. The method failed, i. e., values less than 3 units per hundred cubic centimeters were obtained in approximately 15 per cent of 130 patients with definite or suggestive roentgen evidence of metastasis, the remaining 85 per cent had increases in serum "acid" phosphatase, which in extreme cases exceeded 1,000 units per hundred cubic centimeters. Approximately in 89 per cent of 70 patients without roentgen evidence of skeletal metastasis the values were less than 3 units per hundred cubic centimeters. Of a control group of 570 patients with nonprostatic disease, 90 per cent had serum "acid" phosphatase levels of less than 3 units, 7.5 per cent between 3 and 4.9 units and 2.5 per cent more than 5 units. The conclusion drawn is that the method is consistent and specific enough to be a valuable though not an infallible supplement to clinical, roentgen and other studies for the diagnosis of metastasizing prostate carcinoma. The determination has proved useful in corroborating the diagnosis of metastasizing prostatic carcinoma when suggested by other methods, providing evidence of metastasis from prostatic carcinoma before it is demonstrable roentgenographically or by other methods, determining the prostatic or nonprostatic origin of tumors in patients known to have metastasis, differentiating Paget's disease from metastatic prostatic carcinoma, aiding in the selection of patients for prostatectomy, detecting recurrence in prostatectomized patients, aiding in the selection of cases for androgen control and evaluating and regulating androgen treatment. Case reports from the authors records are cited to illustrate these applications. The important work of Huggins and his associates concerning the effects of castration is confirmed and amplified. Most of the patients showed pronounced clinical improvement following castration.

Diagnosis of Liver Abscess—In the 4 cases discussed, Meredith and his associates made the diagnosis of solitary hepatic abscess by hepatosplenography with thorium dioxide solution as a contrast medium. The precise location of the lesion served as a guide for aspiration. The method appears warranted in all cases in which the diagnosis of hepatic abscess is suspected. The possible potential danger reported by animal experimenters, from the radioactivity of the thorium that remains in the body indefinitely has not been supported by clinical experience. The microscopic study of tissue from 65 patients injected by Yater and Whitmore with thorium dioxide solution for hepatosplenography revealed no evidence of injury to the tissue or any cellular reaction ascribable to the thorium dioxide present. Furthermore, a comprehensive survey of 286 cases covering ten years of experience with the medium in hepatosplenography has revealed no evidence of immediate or remote ill effects in the patients of Yater and Coe. The remarkable point concerning this series of patients was the fact that they have lived longer than was anticipated and have been in moderately good health.

Neuroses and Psychoses in Wartime—Trippe states that the chief predisposing causes of neurosis and psychosis in wartime are in peacetime are neuropathic or psychopathic inheritance and a previous nervous or mental breakdown. Had the 1917-1918 induction board examiners used present day methods, three billion dollars would have been saved the United States for the care and compensation of 97,000 preventable mental casualties. Now rejected neuropsychiatric selectees are returned to their communities to share with others who are easily emotionally dislocated benefits not afforded at the battle front. The preventive measures to be constantly employed among all civilians are play work and knowledge. Recreation should not be merely a side issue. It should be constructively planned to suit each individual. Work should be of the type in which people feel they are doing something for the cause in their all out effort directed toward future peace. Knowledge is an antidote against poisoned morale and too much can never be attained especially for confidence in the body politic against the wide extent of subtle enemy propaganda. The Association for the Advancement of Psychoanalysis best sums up the attitude America must recognize. Under war conditions an increase in anxiety and tension is natural and inevitable. Unless this is realized an individual might consider himself cowardly and contemptible when he is actually sharing a common experience. If anxiety incapacitates an individual then it is most probably not associated with the war and represents a personal problem. Foolhardiness and impulsiveness are not cures for fear. Isolation and isolation from the group heighten anxiety.

Sulfonamides and Local Treatment of Burns—According to Rhoads and his associates, the use of sulfonamide compounds in the local treatment of burns has not, in their hands, obviated the necessity for skin grafting, but they believe that their use has reduced the amount of skin grafting necessary and that their value in preparing granulating surfaces for grafting and in effecting bacteriostasis while the grafts are taking has been immeasurable. They have employed sulfanilamide, sulfathiazole and sulfadiazine in powdered form as a primary and as a secondary dressing after other forms of treatment. The results have been superior to those that they obtained by other methods. Spontaneous epithelization without grafting took place more often and pinch grafts tolerated the sulfanilamide well. The drug has been helpful in depressing the infecting organisms during the five days between the application of the graft and the first dressing, thus successful grafting at an earlier stage was possible. The drugs are freely absorbed through large burns and may give rise to drug fever and other toxic effects. Therefore, in view of the hepatic injury in extensive burns and the occasional toxic hepatitis following some of the sulfonamides, the use of the drugs primarily in extensive burns should be approached cautiously. When an occlusive dressing and the sulfonamide effect is desired, sulfadiazine in triethanolamine, as introduced by Pickrell, should be considered.

Surgery and Gastroscopy in Gastric Tumor—Schindler and Letendre compare the gastroscopic with the surgical observations in 95 cases of gastric tumor, 91 of which were cancerous. In 5 of the 91 cases of gastric cancer the lesion was not seen gastroscopically and in 5 others the lesion seen was wrongly interpreted. Of the others, a sarcoma was mistaken for a polyposis, 1 benign submucosal tumor and 1 benign mucosal tumor were diagnosed correctly and 1 benign mucosal tumor was called cancer at gastroscopy. The number of gastroscopic errors can be reduced with increasing experience. In 4 of the 95 cases the gastroscopist did not commit himself as to the nature of the lesion. In 3 cases gastroscopy revealed lesions not palpated or seen by the surgeon at laparotomy. Further examination proved the lesions to be present. Roentgenography and gastroscopy will yield best results in the diagnosis of gastric tumors when used together. In the series of 91 carcinomas, fifteen failures at the first roentgen examination are compared with ten failures at the first gastroscopic examination. The size and the site of the tumor were determined satisfactorily by gastroscopy. The gross type of carcinoma should be diagnosed at gastroscopy only if the whole circumference of the tumor can be seen.

Post-Traumatic Dystrophy of Extremities—Miller and de Takats discuss the signs and alterations that may contribute to a better understanding and earlier treatment of Sudeck's atrophy. In its milder forms the syndrome is far from being rare. When a sprain or a blunt or minor injury does not show a normal course of events but is characterized by excessive pain, vasomotor phenomena and increased pulsations of peripheral vessels, an early reflex dystrophy should be suspected. The differentiation of an early Sudeck's atrophy from traumatic hysteria is often difficult, as the emotional status of many of these patients is often unstable. The "nervousness and excitability" in the late cases may just as well be the result of many months of suffering and not the cause of the syndrome, which most neurologists still maintain. The osteoporosis is not typical for the syndrome. It does not appear early. When it appears in its spotty form in the small bones of the hand and foot or in the lower metaphysis of the bones of the lower arm and leg four to six weeks after the injury, it is rather characteristic. A diagnosis then can be made but only in conjunction with the clinical phenomena. In the later stages, when the bone atrophy

is diffuse, a roentgen differentiation from other forms of atrophy hardly seems possible. Minor, partial injuries of peripheral nerves coursing superficially between the skin and the bone may sometimes be the initial stimulus for the vasomotor phenomena. The diagnosis of such partial nerve injury would be made more often in the dorsal interosseous nerve in Colles' fracture, the superficial radial and ulnar branches in twists and torsions of the wrist and in injuries to the superficial peroneal, posterior tibial and saphenous nerves (which are often stretched, contused or surrounded by a perineural hematoma) if the examination should be directed toward them in cases of severe pain following trauma. The best prevention for Sudeck's atrophy seems the early and complete fixation of all injuries, without interfering with motion and permitting weight bearing, as Boehler recommended, and infiltration of the site of injury with procaine hydrochloride. Whatever the explanation for vasomotor disturbance in Sudeck's atrophy (arteriolar dilatation coexisting with a capillary spasm), repeated sympathetic block in the earlier stages and sympathectomy in the later, more intractable, cases have been of decided benefit. The infiltrations can be followed by mild physical therapy, which, if used alone, often aggravates the pain and muscular spasm. When organic changes are present, such as shortening of tendons, shrinking of joint capsule, ankylosis and faulty position, orthopedic care is required for full functional recovery after sympathectomy.

Experimental Crushing Injury—Bywaters and Poppak describe a method of producing graded injury in the rabbit. It consists in winding a rubber band round the leg so as to produce an ischemia, which is maintained for four and five hours. The resulting course is hemoconcentration and loss of plasma into the injured area, which becomes swollen and doughy. Azotemia, which is thought to be due in part to the depressed circulation but mostly to the increased tissue breakdown, occurs. Other manifestations of the latter are creatinuria and a depression of the carbon dioxide combining power of the plasma, associated with an increased urinary acidity. There is no obviously gross impairment of renal function that could be measured by the power to concentrate urea although a few hyaline and granular casts, sometimes accompanied by a trace of proteinuria, appear. The condition differs from the human condition of "crush syndrome" only in that renal failure and myohemoglobinuria are absent and as there is ample anatomic reason in the rabbit for myohemoglobinuria to be absent it seems possible that these two negative "occurrences" may be causally related to each other.

Bronchial Factor in Pulmonary Embolism—Jesser and de Takats observed the behavior of the bronchial tree when pulmonary embolism is produced in dogs weighing from 10 to 15 Kg. The embolus was produced by injecting 0.5 cc of a mixture of equal parts of barium sulfate, iron perchloride and

isotonic solution of sodium chloride into the femoral vein. A powerful bronchoconstriction was produced during embolism. This could be abolished by bilateral vagal section and often by sufficient doses of atropine. Mechanical obstruction to the trachea did not produce bronchial spasm. Papaverine usually failed to protect the bronchial tree from this reflex spasm. Clinically the suppression of the widespread autonomic reflexes which occur within the distribution of vagal fibers would decrease the morbidity and mortality from pulmonary embolism, at least atropine did in the animal experiments. Its clinical use, in the presence of bronchial obstruction and hypersecretion, may be objected to by those who feel that the drug increases the viscosity of the bronchial mucus and hinders evacuation. The 28 patients with pulmonary embolism observed at St. Luke's Hospital received the atropine-papaverine mixture. It was given immediately after the embolus was recognized and for four to five days thereafter, three times a day. No massive or patchy atelectasis was seen in this group of patients, indicating that at least this medication does not increase bronchial obstruction to a harmful degree.

Rupture of Pregnant Uterus—Woodhull reports that the uterus of a pregnant woman was ruptured in an automobile accident, the erroneous diagnosis of premature separation of the placenta was made because the patient made a rapid recovery on only supportive treatment. It was assumed that uterine rupture occurred at the time of the accident as the result of a blow on the abdomen. After the fetus and a portion of the placenta were extruded into the abdominal cavity the uterus apparently clamped down very rapidly, causing only a minimal loss of blood. Fetal death must necessarily have taken place within several minutes after the accident. From the standpoint of diagnosis the patient did not exhibit the usual signs associated with rupture of the uterus, that is, evidence of intra-abdominal hemorrhage, shock, accumulation of blood under the diaphragm, abdominal rigidity from radiating to the shoulder or vaginal bleeding. The absence of these signs masked the true gravity of her condition and led to the early mistaken diagnosis. It was only after inflammatory reactions and toxic absorption were in evidence that operation was performed. Once a diagnosis of uterine rupture is made, the decision whether to remove the uterus or to attempt repair is influenced by the parity of the patient and her desire for future pregnancies. Although the outcome in his case was satisfactory, the author emphasizes the fact that early diagnosis and prompt operative treatment are of the utmost importance. First and foremost, shock should be controlled by intravenous fluids and blood transfusion, and a laparotomy should be performed as soon as the patient's condition permits. Clamping the uterine arteries through the vagina while preparations for adequate surgery are in progress has been attempted by some men with success.

Therapy in Staphylococcal Infection—Rigdon and Stookey used staphylococcus antitoxin in the treatment of 2 patients with staphylococcal septicemia. The dose of the antitoxin should always be sufficient to produce an excess of antitoxin in the circulating blood. The minimal dose should be 100,000 units preferably given intravenously. In severe infection with profound toxemia 300,000 to 400,000 units of the antitoxin may be required. One important way in which staphylococci may have an influence on the host is through the effect of their toxin on the parenchymatous tissue. Their exotoxin may be neutralized by specific antitoxin given before the toxin becomes fixed in the tissues. Toxin apparently is present in more than 90 per cent of patients with staphylococcal septicemia. It can produce death or it may be only of secondary importance in the pathologic processes. The effect of chemotherapy depends on their inhibitory influence on bacterial growth. They do not neutralize staphylococcus toxin. Combined chemotherapy and serotherapy may offer the best results in staphylococcal septicemia. The efficacy of any treatment is in direct ratio to the duration of the infection, the toxin producing ability of the organism and the resistance of the host. The therapeutic response is best when treatment is instituted early. Chemotherapy and serotherapy are only adjuncts to surgery.

Chronic Thyrotoxic Myopathy—McEachern and Ross report 3 cases of chronic thyrotoxic myopathy and review the 10 described previously in the literature. This disorder resembles progressive muscular atrophy but is unlike it as it is amenable to treatment. The chief features of the 13 cases are as follows. The sex was predominantly male (11 to 2). The age of 1 of the patients was 24 and the other 12 were between 39 and 62 years old. The main symptoms were weakness and loss of weight with muscular wasting, sometimes symptoms suggestive of hyperthyroidism. The onset was gradual usually leading to hospitalization in a year. The pulse rate was elevated and often the pulse pressure was increased. Tremor of the outstretched hands was prominent and general muscular wasting with fasciculation was pronounced in the shoulder and pelvic girdles and less so peripherally in the small muscles of the hands and feet. The basal metabolic rate was elevated from +14 to +68 per cent in 12 and to +100 in 1. The blood cholesterol was low or normal and the dextrose tolerance was normal or reduced. Creatinuria was present and glycosuria in some. Thyroidectomy resulted in complete recovery. The 3 patients who were not submitted to operation died 2 from respiratory paralysis. The muscular weakness and fatigability may temporarily respond to a prostigmine preparation. Fasciculation appears to be of peripheral origin suggesting that there is an increased concentration of acetylcholine at the neuromuscular junctions or a generally increased sensibility of muscle fibers to the chemical transmitter due to metabolic causes and not to denervation. The increased basal metabolism cannot be attributed to fasciculation, as cases of amyotrophic lateral sclerosis show no such increase despite equally active and widespread muscular twitching.

Renal Impairment Due to Crushing Limbs—According to Eggleton and her colleagues impairment of renal function in dogs under soluble pentobarbital anesthesia ensues after four to five hours during which time both hind limbs have been tightly bound with rubber tubing from the ankle to the hip and the thigh muscles have been compressed in a vise and hammered for a few minutes. Removal of the compression is followed by a definite fall in arterial pressure and by anuria or severe oliguria. In the latter event the urine is deeply pigmented, presumably with myohemoglobin, and the creatinine clearance is low, which might be attributed in part to the low arterial pressure. Restoration of the arterial pressure with intravenous gum-saline solution of ox serum usually initiates or increases the urinary flow, but even if the flow is raised to its initial value with diuretics the creatinine clearance, and therefore the concentrating power of the kidney, recovers to only about one fourth of its original value. Microscopically, the kidneys contained a material within the lumens of the tubules which might have been capable of blocking some of the tubules. The material was particularly concentrated in the terminal portion of the proximal convoluted tubules. There was no consistent relation between the extent of the deposit and the impairment of renal function. In the only dog in which high doses of diuretics would not initiate urinary flow there were mitochondrial changes in the proximal tubule cells indicating the action of a poisoning agent. The available evidence from the study of the dogs appears to show that the renal damage is of the same kind as that in man after comparable prolonged crush injury to the limbs. The evidence suggests that the main factor in the injury may be concerned with an increased permeability of the renal tubules due to a toxic agent released from the damaged limbs.

Mangled Forearm Treatment in Skeleton Splint with Fixed Skeletal Traction D Brown—p 425

Wartime Dermatology—Carslaw discusses his experience with diseases of the skin which began just before the present war. The first part of his experience consisted of six months afloat in a cold or extremely cold climate with a personnel of approximately 500 men, the second part of eighteen months was that of a skin department of a large naval hospital at home and the third consisted of six months afloat in the tropics with a personnel of approximately 1600 men. Little contact was made with centers of population during either time afloat, and fresh food was intermittently available. During the first period the few cases that were encountered consisted of impetigo and scabies and several cases of dermatitis of the hands apparently

due to change from civil to service occupation. During the second part 1,149 cases were seen—652 as inpatients and 497 in consultation. There were (in order of frequency) cases of dermatitis from all causes, scabies, impetigo and mycosis. During the last period 349 cases of mycosis, scabies, miliaria rubra or impetigo were encountered. The following points, according to the author, are of practical value in service wartime dermatology: (1) economy of loss of men hours and of drugs is of national importance, (2) the bulk of medical stores must be kept small, (3) simplicity and, when possible, standardization ease the burden of an overtaxed nursing staff and (4) early diagnosis and treatment save loss of man hours. Ointments could, he feels, be largely discarded, particularly in summer and in hot climates, mercury replaced by aniline dyes and the production of starch poultices curtailed. The best results were obtained by the use of a comparatively small number of remedies, and simplicity saved the time of nursing and dispensing staffs. Early diagnosis and treatment mean a smaller area to treat and therefore a saving of supplies and time lost. In many ways life has been made more simple by rationing in domestic life, and a plea is made that the treatment of cutaneous conditions could and should be simplified to conform with the national war effort. For the treatment of mycosis chrysarobin was used, as the cases were unusually severe and numerous.

Cerebrospinal Fever—From January 1940 through February 1942, 500 patients with cerebrospinal fever were admitted to the Cardiff City Isolation Hospital. They were treated by chemotherapy, Harries says, without antimeningococcus serum intrathecally. The ages of the patients ranged from an infant of 6 weeks who recovered completely to a person of 70 who died. All patients, even those who were moribund and died within a few minutes of admission, were included in the group of 500. The total number of deaths was forty-three. Sulfapyridine was employed in the treatment of 471 and sulfathiazole for the others. Sulfathiazole was as effective in promoting recovery and was less prone to cause nausea and vomiting. The drug was given by mouth in 2 Gm doses on admission and repeated in four hours' time then 1 Gm every four hours for the next seventy-two hours, then 0.5 Gm was given for a further three days. After the first 250 patients were treated the dose was increased to 2 Gm every four hours for four doses and then 1 Gm every four hours for ninety-six hours, followed by 0.5 Gm every six hours for a further three days. The increased dosage had a slight effect in diminishing recurrences and complications, such as arthritis. Children less than 12 were given half the adult dosage, and infants less than 1 received one fourth of the adult dose. In all, 1,935 lumbar punctures were performed without any untoward effect. No general anesthetic was administered. Apart from relieving headache, the reduced intracranial pressure was considered less damaging to the nervous tissue. The cerebrospinal fluid furnished a satisfactory guide to the progress of the disease. No patient was regarded as out of danger if the sugar had not returned to normal. Only six ventricular and five cisternal punctures were necessary. If the patient was comatose the tablets were crushed and given intranasally. If vomiting occurred after ingestion of the drug or the patient was delirious and nasal feeding was difficult, the sodium salt of sulfapyridine was given by intramuscular injection, but as sloughing often ensued in spite of care, it was discontinued and the sodium salt in equivalent doses was injected intravenously with three times its volume of isotonic solution of sodium chloride. Severely ill or greatly dehydrated patients were given the sodium salt of sulfapyridine intravenously in about 500 to 1,000 cc or more of isotonic solution of sodium chloride in 5 per cent dextrose solution by the vacoliter drip method. The ingestion of fluid was encouraged. The patients who had such complications as arthritis or iridocyclitis during convalescence were given a second course of chemotherapy. If bromides were given as sedatives the sodium salt rather than the potassium salt was administered. No person in attendance contracted the disease. Morphologic meningococci were found in 465 cases, or 93 per cent. Material for cultures was obtained from 214, 93 per cent belonged to group 1, 17 per cent to group 2 and 33 per cent were inagglutinable. Clinically, the various strains seemed to be of equal virulence.

Water Borne Outbreak of Paratyphoid B—Jones and his colleagues report the occurrence of paratyphoid fever in a village in which 21 out of 34 of the residents, living in a group of seven cottages built round a court containing a pump from a shallow well, were infected. They excreted *Salmonella paratyphi B* in their feces. First the outbreak was water borne was confirmed by the isolation of this organism from five different samples of the well water in three different laboratories. How the well became infected was not discovered but there was ample opportunity for infection by pollution of the ground in the vicinity.

Lid Retraction in Toxic Diffuse Goiter—Eden and Trotter state that lid retraction is, like exophthalmos, a characteristic feature of toxic diffuse goiter. The two conditions are easily separable clinically though both give the impression of prominence of the eye. Lid retraction was present in 72 of 134 patients with toxic diffuse goiter, in 39 of whom it was associated with true or concealed exophthalmos. Unlike exophthalmos which is apparently extrathyroid in origin lid retraction usually disappears when the thyrotoxicosis becomes inactive, although occasionally it appears or persists in the absence of active thyrotoxicosis. Therefore lid retraction appears to be governed by two factors, one of which is derived from the thyroid and the other must come from another source (possibly the inferior pituitary gland).

Local Absorption of Sulfanilamide—Hodgson and Robinson followed the sulfanilamide blood levels of 41 patients whose wounds, operative or others, were treated locally with the drug. Samples of blood for determination were taken every six or eight hours for the first twenty-four hours, then every twelve hours and finally daily. The value obtained twenty-four hours after operation was within 10 per cent of the peak value, except in 1 case, that of an arthroplasty of the hip. With this same exception the peak value was reached between sixteen and thirty hours after operation. In the case of the arthroplasty the blood sample taken eight hours after operation gave the highest concentration of sulfanilamide. The concentrations have usually been of the order of 1 mg per hundred cubic centimeters of blood for each gram deposited in the wound. In many cases local application alone will maintain an adequate therapeutic level in the blood, so that simultaneous oral administration is by no means always necessary. When the tissue from which absorption occurs is muscle which has a good circulation, the blood concentration attained at the end of twenty-four hours per gram of drug deposited in the wound is in the neighborhood of unity. Indeed, with some wounds care is rather needed lest too much sulfanilamide be applied locally and toxic effects result from free absorption.

Lingual Application of Estradiol—Having demonstrated that testosterone has a much more intensive action when administered by the lingual route Miescher and Gasche investigated the effect of lingual administration of estradiol. The effect of the sublingual administration was compared with that of stomachal administration in a ten day test on 154 castrated female albino rats. In stomachal administration the drug was introduced by a stomach tube. In sublingual application drops were applied to the under surface of the tongue. It was found that alcoholic solutions of estradiol when administered by the lingual route exert an effect which is from ten to twenty times greater than that of stomachal administration. With the lingual administration effects can be obtained on the uterus which are not obtainable by stomachal administration. The estrus test likewise demonstrates a more intense action of the lingual administration. The uterus test, however, is much more sensitive than the estrus test. The efficacy of the lingual administration of estradiol is close to that of percutaneous or subcutaneous administration in the uterus test as well as in the estrus test.

- *Shock Therapy in Typhoid Fever in Children E Peluffo and J M Portillo—p 257

Shock Therapy in Typhoid Fever—Peluffo and Portillo treated 65 children with typhoid fever with shock therapy induced by intravenous injection of antityphoid vaccine in hypertonic dextrose solution. The injections were made at intervals of two or three days. The first dose was 0.25 cc of the vaccine, subsequent doses varied with the age of the patient from 1 to 1.5 cc of the vaccine. Shock therapy by means of antityphoid vaccine had a favorable effect on the course of the disease in 50 per cent of the cases. The earlier the administration the better the results. Severe types of the disease were not influenced by this therapy.

Pulmonary Complications of Diphtheria in Adults—According to Claveaux and Salveraglio, pulmonary complications of diphtheria in adults have received little attention although they prove fatal in the majority of the cases. The

mode of origin and its significance vary according to the time of appearance of the pneumonic process. There is a type of a lesion seen in the course of an extensive laryngotracheobronchial diphtheria. Formation of intrabronchial pseudomembranes produces obstruction of the bronchi, which in turn leads to formation of foci of atelectasis which become rapidly infected and give rise to secondary bronchopneumonia. The authors had the opportunity of studying several of these extensive cases of diphtheria in adults. Signs of diffuse bronchitis with dyspnea and cyanosis are the usual clinical symptoms. Roentgenologic examination reveals multiple pulmonary shadows. Anatomicopathologic study discloses involvement of the entire bronchial tree by pseudomembranes, multiple foci of bronchopneumonia and atelectasis. Another type of lesion is represented by the bronchopneumonia of croup. This is seen more often in children. The authors observed it in a patient aged 21 who on the day after having undergone tracheotomy for croup developed a severe bronchopneumonia which terminated in cure. The pulmonary congestion produced by the diphtheritic toxin, the impairment of the pulmonary ventilation due to laryngeal stenosis and bronchial obstruction by pieces of pseudomembrane and aspiration of blood after tracheotomy are the factors which cause this bronchopneumonia. Acute pulmonary processes in the course of the secondary syndrome and of diphtheritic paralysis represent a special type. Paralysis of the muscles of respiration is the factor chiefly responsible for this form. Paralysis and anesthesia of the larynx make possible the passage of food into the respiratory passages and thus contribute to the production of septic pulmonary processes. These lesions are nearly always fatal. Paralysis of the respiratory muscles is an obstacle to successful treatment in these cases. However, prophylactic treatment can be effective in preventing these complications. The authors recommend careful disinfection of the upper air passages and frequent inhalations of oxygen alternating with carbon dioxide-oxygen mixture. To avoid the passage of food into the air passages in the presence of the paralysis of the muscles of the throat it is advisable to feed the patients by rectum, by the subcutaneous route or by the nasal tube.

Estrone in Treatment of Pigmented Spots—Rocca tells of a woman of menopausal age who developed coffee colored spots on the face particularly about the eyes, in the ciliary and supraorbital region, on the cheek bones and on the arms and knees. Microscopic examination of an excised spot from the arm indicated that they were not pigmented nevi. Disturbances in pigmentation frequently result from endocrine disturbances of the menopause, although they are rarely as severe as in the case cited here. Twice a week, for a period of several months 5,000 international units of estrone was administered by injection. The menstrual disturbances became regulated, the subjective symptoms improved and the facial spots began to clear up. An estrone ointment was now applied to the facial spots for twenty days. It was observed that some spots disappeared and others became much lighter. Local and injection treatments were continued for several months, when the pigmentation had decreased greatly on the face and in many parts of the body. When the endocrine treatment had been interrupted for a year, small spots began to appear in the ciliary region.

Idiopathic Diverticula of Duodenum M S Gutarte—p 135
Subarachnoid Meningocele of Sacral Region A Gutierrez—p 156

Endometriosis—According to Ahumada and collaborators perforating posterior endometriosis is rare. It is more frequent in young women. Symptoms, as a rule, are the same as in pelvic endometriosis. Small, acyclic, intermenstrual metrorrhagia, pressure on the rectum or stenosis of same, are the most frequent symptoms. A characteristic finding during gynecologic examination is a hard nodule located behind the cervix, extending laterally and infiltrating the parametrial tissue and the uterosacral ligaments. The tumor may invade the rectal wall. In the early stages the vaginal mucosa is hard inelastic and congested. In the advanced phase a more or less large

tumor or a polypoid formation on a hard neoplastic base is present. Diagnosis in the early and late stages is difficult. The clinical history of the patient, changes in the tumor during menstruation and aggravation of the symptoms during menstruation are suggestive. The diagnosis is verified by biopsy. Surgical therapy varies with the stage of the disease. In the early stage the operation consists of a total removal of the endometriosic plate through a median laparotomy with a subtotal hysterectomy and bilateral salpingectomy. Surgical castration is indicated in advanced cases and roentgenologic castration in the far advanced cases.

Panmyelophthisis Following Arsphenamine Therapy—Rof Carballo and Parras Benito report a case of aplastic anemia with leukopenia and granulocytopenia as well as with hemorrhagic diathesis following combined arsphenamine and bismuth therapy. The extremely grave condition improved following repeated small blood transfusions. During the period of severest anemia, puncture of the bone marrow yielded only fat, but during recuperation it was slowly transformed again into normal bone marrow. The clinical improvement was indicated in advance by an increase in monocytes in the peripheral blood. The good result of the treatment in the extremely severe case indicates that small blood transfusions should be given repeatedly, particularly in cases of aplastic anemia or panmyelophthisis, in which the presence of monocytes indicates that the prognosis is not entirely hopeless. Even if puncture of the bone marrow repeatedly shows its total aplasia, this does not justify the neglect of an energetic stimulation of the hemopoietic organs.

Plasma Transfusion in Hepatic Cirrhosis—Jimenez-Diaz and his associates demonstrated in 1929 that in experimental hepatic disorders produced by chloroform the alteration of the hepatic parenchyma was accompanied by a diminished protein content of the plasma and by albumin globulin inversion. Wallich demonstrated an identical disturbance. The authors investigated the effect of the administration of different types of albumin on hepatic cirrhosis. Intravenous injection of plasma proteins rapidly restored the total protein content of patients with hepatic cirrhosis. The efficacy of mercurial preparations is enhanced, and even without these the diuresis is improved. The development of ascites is arrested, and in 1 patient reabsorption was obtained.

Stomach in Pellagra—Diaz-Rubio and Lara Roldan made roentgenologic studies of the stomach in 255 patients with pellagra. Most noteworthy feature was diminution of gastric peristalsis which often gave rise to great dilatation and retarded

evacuation of stomach contents. The mucosa was atrophic in over 67 per cent of the cases. The atrophy was diffuse in the majority of the cases and limited to certain zones in 16 per cent. A number of patients presented intense aerogastria and a few had large amounts of mucus. In 22.35 per cent of the cases roentgenologic appearances of the stomach were normal as regards the tonus, peristalsis, evacuation and relief of the mucosa, in spite of the fact that pellagra was fully developed. There were some cases in which no relationship existed between the severity of the changes and the gravity of the clinical picture, but in 59 patients, on whom at least 3 studies were made, there was a close parallelism between the clinical picture and the intensity of the radiologic signs. Roentgenologic examination of the intestine disclosed severe aerocoly, inflammation of the large intestine and retention of the contrast meal in the terminal loops of the ileum. Comparison of the roentgenologic appearance of the gastric mucosa of these patients with those of achylia, suggests that the organic changes in the mucosa are sequels to the functional disturbances.

Sulfapyridine in Asthma—From observation and experimental studies Jimenez-Diaz and his collaborators gained the impression that bacterial infection plays a part in some cases of bronchial asthma. Ten patients with true "status asthmaticus" who for months had proved refractory to various methods of treatment were given sulfapyridine. In 8 of these this therapy effected the disappearance of all symptoms, in 2 the drug was without effect.

- Evolution of Neurologic Thought in Neurobiology J O Trelles—p 137
 Cerebral Tuberculosis J Voto Bernales—p 165

Cerebral Tuberculosis—Voto Bernales found in a study of 22 cases of brain tuberculosis that the process is always secondary to tuberculosis elsewhere. The method of dissemination is most likely the hematogenous. Tuberculous encephalitis and especially tuberculous meningitis are the main terminal clinical types of the disease. Tuberculosis with symptoms of epilepsy and of mixed forms of the disease are terminal clinical types less frequently seen than the foregoing. In many cases the disease develops without symptoms. The diagnosis of asymptomatic types is difficult. It is based mainly on the existence of tuberculosis elsewhere. Cerebral tuberculosis pursues a slow progressive course and leads to grave symptoms. Spontaneous recovery is extremely rare. There is neither a proper medical nor surgical therapy for the disease. The treatment consists in general care of a tuberculous patient and in decompression by trephining when indicated.

Lesions Produced by Light Metals—As a physician in an airplane factory Sedlacek frequently encountered inflammations following cut injuries with duraluminum. These inflammations are mostly seen in wounds too small for surgical care. Large wounds caused by duraluminum are excised and sutured. Subsequent inflammations are rare. The appearance of a blister filled with serous fluid is characteristic of an unexcised duraluminum lesion. The blister is usually in evidence from one to two days after the injury. The contents of the blister suppurate, and in some cases necrosis develops at the base. The inflammation spreads to the surrounding tissues, and a lymph-

angitis or a lymphadenitis may develop. In addition to dermatitis, conjunctivitis and gastritis may develop. These lesions can be explained by the mechanical action of duraluminum dust, which develops in the course of drilling, can be inhaled or swallowed and, although extremely fine, may cause epithelial defects in the mucosa. Allergy does not play a part, because cutaneous tests were always negative and the blood tests made by Utz failed as a rule to disclose eosinophilia.

Electron Microscopy in Asbestosis—Kuhn says that because the asbestos used in factories is mostly serpentine (chrysotile) asbestos and not so much hornblende asbestos, it was generally believed that the asbestos substance found in lungs with asbestosis is chiefly serpentine asbestos. Studies by Sundius and Bygden disclosed, however, that only hornblende asbestos is demonstrable in the lungs, which seems to suggest that serpentine dust is decomposed in the tissues. Kuhn used the electron microscope to study form, size and structure of asbestos dust and the asbestos found in the lungs. It was possible to detect a considerable number of asbestos dust particles that were below the threshold of the ordinary microscope. The needles of chrysotile asbestos appear under the electron microscope curved, clear and transparent. The needles of hornblende asbestos are rigid and curved pieces are rare, their diameter is usually greater than that of serpentine (chrysotile) asbestos. Needles were isolated from 3 lungs with asbestosis. Their examination under the electron microscope disclosed size and form but did not aid in deciding whether the asbestos was chiefly of the serpentine or of the hornblende type. For this reason it was decided to employ the photomicroscopic determination of the refraction exponent as suggested by Sundius and Bygden. This method revealed that the large asbestos needles isolated from the lungs were of the hornblende type. It is concluded that serpentine asbestos is decomposed in the lungs and is the essential cause of fibrosis. If asbestosis lungs are macerated with nitric acid and hydrogen peroxide not only are free asbestos needles obtained but also asbestosis bodies. Hornblende asbestos shows no signs of decomposition by the organism either in the free needles or on the asbestosis bodies.

Silicosis of Intrathoracic Lymph Nodes—According to Hagen, reports on silicosis as well as the legal regulation concerning compensation for occupational disease are concerned chiefly with silicotic changes in the pulmonary tissue. He describes several cases of complicating severe silicosis of the intrathoracic lymph nodes with a fatal outcome. The first patient, a man aged 63, had comparatively slight silicotic changes in the lungs, but there existed a severe silicosis of the lymph nodes at the bifurcation, which by severe cicatricial shrinkage led to the formation of 3 traction diverticula in the esophagus. Perforation of a diverticulum led to pulmonary abscess formation, bronchiectasis and generalized suppurative bronchitis. The fatal outcome of the pulmonary abscesses must be regarded as the result of silicosis. Several additional cases are described and evaluated and the conclusion is reached that silicosis of the lymph nodes, if it becomes the point of origin of a severe disorder, must be regarded as a compensable disorder, just as severe silicosis of the pulmonary tissue.

Nervous System in Manganese Poisoning—Voss maintains that the anatomic basis of manganese poisoning has not been clarified. Neither the few histopathologic studies on human subjects nor animal experiments have given reliable results. Changes regarded as specific for manganese poisoning could be explained also as the result of complicating disease or as caused by the age of the patient. The assumption that the clinical manifestations of manganism are due chiefly to extrapyramidal motor lesions, particularly an impairment of the pallidum, has not been definitely corroborated by anatomic findings. In view of the fact that the clinical symptoms of manganism resemble those of paralysis agitans and postencephalitic parkinsonism, changes could be expected in the substantia nigra. However, this region was found completely intact, not only by earlier investigators, but also by the author, who studied this region in 2 cases. Examination of the spinal cord and peripheral nerves of patients with manganese poisoning has been largely neglected hitherto. Whereas in the 2 cases reviewed by the author the

brain was found to be practically normal, important changes were seen in the spinal cord and in the peripheral nervous system. In one of the patients the manganese poisoning had taken an atypical course. Amyotrophic lateral sclerosis with bulbar symptoms dominated the clinical picture, and anatomic studies disclosed corresponding changes. The second case presented classic symptoms of manganism. As is frequently observed in manganese poisoning, certain pyramidal symptoms were present, but changes in the peripheral nerves were not to be suspected. Anatomic studies disclosed extensive degeneration in the right lateral pyramidal tract and in both sciatic nerves with pronounced vascular disturbances in the diseased regions. Other nerves had not been examined. The author is convinced that manganese poisoning was the cause or at least a contributing factor of the described changes. Studies should be made not only of the brain but of the spinal cord and the peripheral nerves as well.

Syphilis of Aorta. Changes in Frequency and Symptomatology During Last 20 Years H. Deitert—p 258

Seasonal Changes in Circulatory Factors—Paul studied seasonal changes in the pulse frequency, in the blood pressure at rest and after exertion, in the values derived therefrom and in the vital capacity on 900 healthy men between the ages of 17 and 30. The pulse rate during rest, as well as after exertion, showed noticeable seasonal changes. The maximum was observed during the winter months, January to March, the minimum during the summer months July to September. Seasonal fluctuations in the blood pressure could not be clearly established. The product of amplitude and frequency, in spite of considerable scattering of individual values, clearly showed an annual curve, the maximum is in March, the minimum in September. However, no seasonal fluctuations could be detected in the exertion values. The vital capacity shows an extremely low minimum in June.

Increased Thyroid Activity and Altitude Tolerance—Rotter made animal experiments to determine whether increased thyroid function would modify altitude tolerance. He treated guinea pigs with thyrotropic hormone so as to increase the thyroid function and to intensify tissue combustion. These animals, together with normal controls, were subjected to short term experiments in the low pressure chamber. It was observed that the animals which had been treated with thyroid had respiratory arrest at a time when the untreated animals still felt comparatively well. Comparative electrocardiographic tests, made at intervals, disclosed that the hearts of the guinea pigs which had been pretreated with thyroid were much more vulnerable to oxygen deficiency than those of the untreated controls. The pretreated animals showed during the experiment a greatly increased sympathetic tonus. Microscopic examination of the organs, however, permitted no conclusions regarding the greater sensitivity to oxygen deficiency of the pretreated in comparison with the untreated animals.

Spontaneous Desensitization in Occupational Eczema—Koch states that follow-up examinations on patients with occupational eczema who had been advised to change their occupation revealed that many had not followed the advice. The majority of the patients remained subject to eczema, but

some had lost it in spite of further contact. Of 131 patients, 20 showed this contradictory behavior. Among the 60 bakers who were reexamined there were 10 in whom the eczema had disappeared and among the 71 persons of other occupations there were likewise 10. The explanation of such spontaneous cures and the underlying processes are of considerable interest. Regular weekly observations on 8 patients disclosed two different forms of development. One group of 5 patients experienced at every resumption of work first a considerable exacerbation of the disorder, usually with the aspects of an acute eczema, with considerable inflammation and itching. However, in spite of continuing the work there now followed, in contradistinction to earlier attacks, a gradual regression of the manifestations, which finally resulted in a complete or an almost complete disappearance of the eczema. Small foci recurred occasionally but these could be controlled with simple measures. They did not necessitate the interruption of the occupation. However when work was resumed after it had been interrupted for a while on account of holidays, vacations or layoff there was a renewed exacerbation, which, however was followed by almost complete freedom from complaints. The course in the 3 other cases was somewhat different. In these too the eczema recurred on the hands when work was resumed, that is, at the sites where it had been originally and which were chiefly exposed to the offensive substances. Later the lesion on the hands healed and recurred at other sites of the body, in 1 case at the border of the original eczema, which now had disappeared. The recurrence was so mild that the working capacity was not impaired. The author thinks that the only possible explanation is a desensitization, which presupposes specific allergic processes. He explains the difficulties encountered if an explanation is attempted and believes that eczema is not a pathogenic unit. Various other factors besides the allergic may play a part. Results of artificial desensitization carried out for therapeutic purposes have been slight. This therapeutic method cannot be generally recommended but it should not be completely abandoned. Further observations may disclose regularities which may become the basis for more favorable results.

- *Physiologic and Chemical Studies on Patients with Latent Allergy as Contribution to Problem of Allergic Constitution. G. Albus —p. 592

Physiologic and Chemical Studies in Latent Allergy.—According to Albus the basis of allergy is not purely serologic but the still largely unknown process in the body cells which is probably more of a physiologic or pharmacologic nature. The author describes physiologic and chemical studies on non-allergic persons and patients with latent allergy. The latter were clinically healthy persons with a history of allergy. The studies concerned serum protein, serum globulins, serum calcium, blood sugar, serum cholesterol, histaminase and acetylcholine esterase. It was found that as regards serum protein serum calcium and blood sugar there was no difference between nonallergic and allergic persons. The globulins seem to be increased in allergic persons. It is suspected that the cholesterol ester is reduced in the serum of allergic patients. The activity of histaminase and choline esterase of the blood is noticeably decreased in allergic patients. The author discusses sensitization, antigen antibody reaction, histamine and histaminase, development of allergic reactions, secondary effects of allergic reactions and the allergic constitution and its modification. He sets forth the hypothesis that the allergen resorption as well as the antigen antibody reaction are for every individual continuously evolving normal physiologic processes. The person with an allergic constitution, because of the reduced activity of his histaminase and choline esterase has an increased suscep-

tibility to histamine and acetylcholine. It is suggested that the more comprehensive term "histamine susceptible constitution" be substituted for "allergic constitution." There are still problems that require investigation, such as the role of epinephrine oxydase in allergy. Experimental studies demonstrated that the increase in serum globulins in allergic persons is due to their increased concentration gradient for histamine, because in animal experiments sensitization and frequent small doses of histamine effect a noticeable increase in serum globulins, in tests on human subjects glutathione, ascorbic acid and thiosulfate produce reduction in the serum globulins. The author denies that a colloidoclastic crisis is a prerequisite for the development of an allergic reaction. He suggests that insufficient negativity of the redox potential is the deeper cause of the histamine susceptible constitution. Administration of large quantities of vitamin C does not seem to solve the problem of treatment in allergy. The cardinal problem is how the organism can be influenced to return and properly utilize the redox substances. A blood transfusion has been known to improve the storage capacity for vitamin C in a case in which vitamin therapy had been a failure previously. Although there is as yet insufficient evidence for the administration of redox substances, it is essential to keep away from the allergic patient all substances that impair the redox potential.

Sensitivity to Odor of Horses and Horse Serum Hypersensitivity.—Hartmann investigated the question of a relationship between sensitivity to the odor of horses and hypersensitivity to horse serum. He inquired of 1668 persons (1) whether they were sensitive to the odor of horses (2) whether they ever received an injection of horse serum and (3) whether, in doing so, they developed signs of serum disease. The group included men in military hospitals and men, women and children in a city hospital varying in ages between 5 and 65 years. The inquiry disclosed that 26 or 1.55 per cent were sensitive to the odor of horses. Of the 26 7 had previously been treated with horse serum and none had had signs of serum disease. Only 1 of 17 persons sensitive to horse odor given an intracutaneous injection of 0.1 cc of horse serum developed a mild local reaction and this person had received tetanus serum one month previously. Of the 1647 persons who were not sensitive to the odor of horses 171 had been treated once with horse serum, and of these 16 had had signs of serum disease. The intracutaneous injection of 0.1 cc of horse serum into 10 persons not sensitive to the odor of horses, but previously treated with horse serum without showing signs of serum disease, resulted in a local reaction in only 1. Ten children not sensitive to the odor of horses, but who had been treated from three to five weeks previously with diphtheria or scarlet fever horse serum were also given an intracutaneous injection of 0.1 cc of horse serum. Among these there were 4 who showed a mild reaction around the site of injection. It was thus impossible to establish a relationship between sensitivity to the odor of horses and hypersensitivity to horse serum. Testing fluids were extracted from the urine, sweat and cutaneous scales of horses, and these were used for intracutaneous tests on persons sensitive and not sensitive to the odor of horses. These tests again failed to reveal a relationship between the sensitivity to the odor of horses and to the aforementioned extracts. Eating of horse meat caused no reactions in 2 persons who were sensitive to the odor of horses. The author concluded that there is no connection between sensitivity to horse odor and hypersensitivity to horse serum.

Book Notices

The Pathology of Trauma By Alan Richards Moritz, M.D. Professor of Legal Medicine, Harvard Medical School, Boston. Cloth. Price \$6. Pp. 386 with 117 illustrations. Philadelphia: Lea & Febiger, 1942.

The purpose of the author is to compile a volume which is primarily devoted to the pathogenesis, pathologic anatomy and histology of traumatic lesions which have not hitherto been adequately treated in the literature. Topics which have been satisfactorily considered are discussed briefly in the interest of completeness. The general plan of the book is satisfactory, the chapter arrangement beginning with a general consideration of mechanical injuries including various types of trauma—gunshot wounds, stab wounds and injuries due to blunt force. Other sections are devoted to trauma and infection, trauma and tumor and then follows a discussion of the lesions of the various body systems, special organs and tissues, their complications and sequelae. Attention has been given to controversial questions, notably in the chapter on trauma and tumors and in the discussion of the productive mechanism of cerebral concussion, and Moritz's reasoning is in agreement with generally accepted opinions. To those who are unfamiliar with recent advances in forensic investigations the information on the various laboratory procedures for testing discharged powder residues on the skin and clothing in gunshot wounds, the use of infra-red photography in the examination of the clothes in these cases and the utilization of ultraviolet rays in other investigations may be of interest. The section on injuries resulting from detonation of high explosives is also particularly pertinent at this time. Many other parts of the book are informative, especially the discussion of the exacerbation of diseases by trauma and the section on asphyxia of traumatic origin. Adequate references are given for those who wish to pursue further the topics which are under discussion. The illustrations are excellent and clearly depict the points which the author wishes to emphasize and are conveniently located in relation to the text. While there are a few minor omissions and the index could be improved on, generally considered the book will be a valuable addition to the library of the student of forensic medicine as well as of clinicians and pathologists, for whom the book is intended. Incidentally it collects in one handy and convenient volume much information which would otherwise necessitate an exhaustive search of the literature.

Food Charts. Foods as Sources of the Dietary Essentials. Prepared by a Joint Committee of the Council on Foods and Nutrition of the American Medical Association and of the Food and Nutrition Board of the National Research Council. Paper. Price 10 cents. Quantity prices on request. Pp. 20. Chicago: American Medical Association, 1942.

This well illustrated essay is an interesting and forceful presentation of some of the recently acquired quantitative information about foods as sources of the dietary essentials. It has been prepared by a joint committee of the Council on Foods and Nutrition of the American Medical Association and of the Food and Nutrition Board of the National Research Council. There are eight charts which show the contribution of individual foods to the needs for protein, calcium, iron, vitamin A, thiamine, riboflavin, nicotinic acid and ascorbic acid. A feature of these graphic presentations is that the values are presented in terms of the percentage of the daily requirements which are supplied by typical servings of each food. The requirements selected are the Recommended Daily Allowances of the Food and Nutrition Board of the National Research Council. The charts show, for example, that a serving of about $3\frac{1}{2}$ ounces of cooked greens (beet, kale, chard, mustard, spinach, turnip) will supply more than 10,000 international units of provitamin A, the daily allowance of which is 5,000 international units. An orange of average size, half a grapefruit or a serving of fresh strawberries will supply the 75 mg. of ascorbic acid which is considered to be a desirable intake of vitamin C. It is interesting to note the unique value of milk as a source of calcium, protein and riboflavin. There is a descriptive paragraph or two about each of the charts. In addition the booklet reproduces the table of Recommended Dietary Allowances and also provides the values of Minimum Dietary Requirements developed by the Food and Drug Administration for purposes of labeling special dietary foods. This little booklet thus provides a considerable amount of information about foods.

History of the School of Nursing of the Presbyterian Hospital, New York, 1892-1942. By Eleanor Lee, A.B., R.N., Assistant Professor of Nursing, Department of Nursing, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price \$3.50. Pp. 286 with 57 illustrations. New York: G. P. Putnam's Sons, 1942.

Rarely does one find a volume so free from flaw as this one by Miss Eleanor Lee. Her knowledge of the Presbyterian Hospital, coupled with her being well versed in the history of nursing, makes her especially qualified for just such a work as this. That she has done it with real skill is revealed through the contents, with ten chapters, over fifty illustrations, a chronological list of events from 1892 to June 1942, an appendix, pages of which are original copies in facsimile, junior and senior lectures, 1893-1894, graduating exercises of the class of 1894 in the Training School for Nurses, with notes from diaries of members, the history and significance of the Presbyterian nurse's pin, speakers at graduation, 1894-1942, presidents of the alumnae association, a prayer offered at the funeral of Miss Maxwell, Presbyterian Hospital School of Nursing Hymn, hospital officers administrative staff, nursing service, Faculty of Medicine of the College of Physicians and Surgeons, officers of instruction, Department of Nursing, plan of instruction, 1942, explanation of table of trends in nursing, bibliography, and a helpful index.

To select one feature as most prominent is difficult but through the table of contents one sees what ground is covered, and one needs only to go through these chapters to see how great a piece of work this has been, with method most meticulous, attention to minute details and thoroughness by the author, all of which make the volume increasingly valuable with all its information and also as a tool of reference. Each chapter has its own part in forming the whole, many having worthily contributed toward making the volume all that it is, and, where mention can not be made in the contents, mention is made in the index, as in the case of the Florence Nightingale Memorabilia, easily beyond compare and as delightful in its way as is the chapter on the Alumnae Association.

Chapter I is chiefly devoted to the Presbyterian Hospital in its early days at the time of its opening on Oct. 10, 1872 and, as its title implies, the Presbyterian Hospital before the establishment of the Training School for Nurses. Mention is made of its benefactors and various organizations, how middle aged women were employed as nurses, with their training gained through experience and with the help of doctors, up to 1891, when, because of increased demands on the hospital, and in awareness of the great possibilities the work of nursing might extend, decision was made to establish its own training school.

With chapter II, on the founding and early development of the Training School for Nurses, the Training School for Nurses was opened in May 1892, Miss Anna Caroline Maxwell having taken over her duties as superintendent of nurses on January 1 of that year. From the time of her appointment until her retirement in June 1921, constant progress was made through the untiring and devoted service of this gifted woman, all of which has been ably continued by Miss Helen Young, acting director at the time of Miss Maxwell's retirement, who was made director of the Nursing Service and the School of Nursing of the Presbyterian Hospital in 1923.

To both of these praiseworthy women the author has given high merit, as well as to others where merit was due, thus reflecting merit on herself, equally deserved. From the time the Training School for Nurses was born, all worked loyally, perhaps little dreaming on "how firm a foundation"—toward what has now become the Department of Nursing of the College of Physicians and Surgeons, Presbyterian Hospital School of Nursing,—a monument of service to serve all "without regard to race, creed or color." Credit should also go to the publishers, who have done fine work with their neat binding, paper, print and entire format, adding their part to a work already easily readable. It is a volume that should find an early place not only in all medical and hospital libraries, but in public libraries as well, as also in the hands of doctors and countless lay readers, for all of whom it will arouse interest in history not yet awakened and stimulate that already alive in the many who long since have learned the joy of all that is historical.

Massage Manipulation and Local Anesthesia By James Cyriac M D B Ch Assistant Medical Officer Physiotherapeutic Department St Thomas's Hospital London Cloth Price 12s 6d Pp 302 with 26 Illustrations London Hamish Hamilton Medical Books 1941

This monograph opens with the statement that "this work is intended primarily for graduate masseuses and for the medical practitioners from whom they receive instructions" In the United States most medical men instructing physical therapy technicians would not recommend the book to their students because many of the procedures described have never before been published and many of the techniques presented would have to be verified by a physician before he could recommend them

Among the many subjects dealt with for the first time, attention may be drawn to the author's technique for the treatment of spastic conditions of the alimentary tract by manipulation of the intestine The author believes that great improvement, even cure of long standing abdominal disorders, can be achieved by manual treatment of the gastrointestinal tract Considerable experience and the use of controls will be required to substantiate the author's statements "Paradoxically enough constipation is harmless as long as no effort is made to treat it by taking laxative medicines" and "If the perineum is lax, the tone of the levator ani muscle can be restored by active exercises even years after childbirth" Cyriac outlines the material on a regional basis and gives the conditions in each region that are amenable to the application of physical therapy His theories have been evolved over a period of years in the course of a systematic reevaluation of long established methods Their advantages have been amply demonstrated to the author and his colleagues in the physical therapy department of St Thomas's Hospital His approach to the subject matter is practical Although the book is thought provoking the theories presented will need further investigation especially by physical therapy physicians

Los Angeles County Hospital House Staff Manual Edited by Morris F Colten M D Third edition Paper Price \$3 Pp 342 with 1 Illustration Los Angeles 1942

This manual prepared for the guidance of the house staff of the Los Angeles County Hospital, has been completely revised since the publication of the second edition in 1941 It is a treatise of modern practice and is sufficiently comprehensive to cover the essential needs in relation to general rules and regulations, minor technical procedures, the hospital formulary, diet outlines, laboratory procedures and other departmental routines These standardized procedures should prove exceedingly helpful to new house officers, who must necessarily consolidate and systematize their knowledge in order to function efficiently in a complex hospital organization Directive outlines are included with reference to physical therapy, radiation therapy, general medicine, contagious diseases, pediatrics, neuromedicine, neurosurgery, general surgery, anesthesia, urology, orthopedics, fractures, gynecology, obstetrics, dermatology-syphilology, ophthalmology and otolaryngology There are special sections on sulfonamide therapy, war gases, burns, immunization procedures, public health regulations and psychiatric studies Full directions of diagnostic and therapeutic methods are included in all outlines The present volume can be highly recommended as a model for other hospitals seeking to develop a suitable "procedure book" for their own needs

Emergency Care By Marie A Wooders B S R N Principal School of Nursing Hackensack Hospital Hackensack N J and Donald A Curtis M D Lieutenant Colonel Medical Reserve Commanding 342d Medical Regiment United States Army Hackensack Cloth Price \$3 50 1p 560 with 201 Illustrations Philadelphia F A Davis Company 1942

The title of this book implies correctly that it is more than just another manual on first aid Col Walter P Davenport states in a foreword that in addition to fulfilling its purpose as a nurses' manual for service in national and civilian emergencies it will prove of assistance to nurses in their professional duties and will orient them in the realities of nursing as modified by the necessities of military service The book is divided into sections devoted to general emergencies, hospital accidents, accidents due to individual activities—home and farm accidents—occupational emergencies—camp school and industry—public

emergencies (major disasters) and national and civil emergencies This results in some problems in arrangement, such as the separation of the newer methods of treating burns, which appear under General Emergencies, from another discussion of burns which appears under Home and Farm Accidents, the latter dealing principally with prevention—use of matches, hot liquids and the like This is, however, a minor drawback for any one who reads through the whole book The section on the control of hemorrhage by pressure over blood vessels is illustrated by an osseous skeleton rather than the conventional figure showing the blood vessels Many sections are delightfully illustrated with little sketches which resemble cartoons and which carry their message well The final section includes chapters on administration in army hospitals, organization of the army medical department and similar discussions, which should prove invaluable for any nurse about to enter one of the services The book can be recommended to nurses whether in civil or military life

Public Health Statistics By Marguerite F Hall M A Ph D Assistant Professor of Public Health Statistics School of Public Health University of Michigan Ann Arbor Cloth Price \$3 50 1p 408 with 41 Illustrations New York & London Paul H Hoeber Inc 1942

In the field of public health even more than in that of clinical and laboratory research a thorough knowledge of the handling of statistics is imperative This book has combined a common sense view on the interpretation of public health statistics with a clear and concise presentation of the algebra involved Miss Hall who is assistant professor of public health statistics in the School of Public Health at the University of Michigan gives prominence to the limitations of the statistical method by citing Quetelet's four rules 1 Have no preconceived ideas 2 Be unbiased 3 Attract your problem with an open mind 4 Do not reject contrary values Eliminate possible errors then seek verification of the contrary values 3 Face the facts you find 4 Compare data that are comparable Accurate comparison can be made only between similar things and over short periods of time Data drawn from unlike sources may lead to false interpretations These rules are sound for any scientific method and the fact that they are applied to statistics is merely evidence of the scientific acceptability of statistical methodology

Of special interest to prospective contributors to THE JOURNAL is the following exercise given at the end of one of the chapters Select a table published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION Give its fundamental weaknesses and make a skeleton table which would more nearly conform to the theoretical ideals of statistical tabulation Though not all tables in THE JOURNAL can be used as horrible examples, most writers on clinical subjects have been inclined to neglect the principles of proper statistical treatment of their data Herein lies a useful reminder

Bernard creador de la medicina científica Estudio crítico de su labor científica seguido de una versión castellana de su Introducción al estudio de la medicina experimental Por el Coronel M C Jose Joaquin Izquierdo profesor de Biología experimental en la Escuela médico militar y en la Facultad de medicina de la Universidad Nacional de México México D F Paper Price 20 pesos Pp 329 Mexico D F Imprenta Universitaria de México 1912

The interest in Claude Bernard on the part of Mexican investigators is praiseworthy The first translation of Introduction à l'étude de la médecine expérimentale (Paris 1865) appeared in Mexico in 1880 The second and more concise translation itself a classic, by don Carlos Garcia (1900) was published in the somewhat obscure village of San Luis Potosí The Garcia translation has been missed by most of the collectors of Bernard and indeed the author of the book under review belatedly admits neglecting the mention of it in his outline of studies in physiology in Mexico, Balance cuatricentenario de la fisiología en México (1934) The present work is an excellent treatise on Claude Bernard, as it includes not only biographic material but a careful analysis and descriptions of Claude Bernard's most significant experiments The bibliography, although incomplete, is sufficient to support the text and, on the whole the book is to be recommended not only to medical historians but to physiologists as well

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

EFFECT ON SKIN OF HEAT AND COLD

To the Editor—Please inform me if the tissue changes such as those due to thermal changes can be called burns? Specifically, can the changes produced by the action of solidified carbon dioxide on tissue be called a burn? Also what are the essential physiologic and pathologic differences in heat or cold on tissues? I have heard that ice application or hot water bag application makes little difference as used on tissue, as for example in acute appendicitis. In other words, either ice or heat may be used to get the same result.

M D California

ANSWER—Changes in the skin from the use of solidified carbon dioxide are often spoken of as burns. Burns as ordinarily understood, however, mean injuries from heat. Perno is a term often used in connection with the results from exposure to cold. The tissue changes that follow the use of cold differ from those from heat.

According to Sonnenburg and Tschmarke (quoted by Gans, Oskar, *Histologie der Hautkrankheiten*, Berlin, Julius Springer, 1925, vol 1, p 175) it is customary to divide the frostbites into various grades analogous to those for burns but it is necessary to bear in mind that this classification is based on a purely superficial resemblance of the symptoms devoid of any pathologic justification. Thus one may distinguish between erythematous, bullous and gangrenous dermatitis. The first is marked by a vascular dilatation following a fleeting constriction. A short period of paleness is followed by a bluish red discoloration, swelling and definite itching of the skin, the result of a passive hyperemia. In this condition complete restitution is still possible. If, however, the action of cold and hence the venous accumulation is continued, the increased swelling will be associated with anesthesia of the whole area. Later the formation of serous vesicles is noted, developing into hemorrhagic ones if the damage is deeper. Their disintegration is followed by long lasting ulcers—the second stage of the freezing. At this stage a certain forecast of consequences is no longer possible, since these sequels are largely correlated with impairment of the vessels, which can be gaged only in the course of time. The highest degree of freezing is marked by a deep blue-red discoloration of the whole skin, which is completely anesthetized. A necrosis involving cutis, subcutis and often also the muscles, even all the soft parts together with the bony structure, may lead to the destruction of whole parts. This necrosis usually appears as a dry or moist gangrene, depending on whether the elimination proceeds aseptically or with a secondary infection with all its consequences.

SULFUR PREPARATIONS USED FOR MITES AND HUMAN HEALTH

To the Editor—Kindly let me know whether or not there are any health hazards to workers in citrus groves, connected with the spraying or dusting of sulfur preparations for the control of rust mites. The preparations used are a fine sulfur dust, a so called 'wetable sulfur' and a lime sulfur.

Edward J. Kempf, M.D., Wading River L. I., N. Y.

ANSWER—"Wetable sulfur" is sulfur which has been ground with some wetting agent so that on addition of water the mixture is wet easily and the sulfur does not float on top, as would be the case if plain powdered sulfur was used. The preparation known as "lime sulfur" is a polysulfide of calcium, approximately of the formula CaS_2 , made by boiling sulfur with lime and filtering.

The use of wettable sulfur preparations under ordinary field conditions should involve no special health hazard except, possibly, for an occasional instance of sulfur dermatitis in hypersensitive persons.

It is possible that in the practical use of lime sulfur small amounts of sulfur dioxide or hydrogen sulfide might be formed. However, as far as can be ascertained the only health hazard from lime sulfur as normally used may be a dermatitis in susceptible individuals. It might be stressed that in concentrated solution, lime sulfur may act as a powerful depilatory, and at least one instance has been seen in which such a solution caused burns of the skin. In actual use as an insecticide the preparation is used in such dilute form that its caustic effect is probably not noticeable.

DIFFERENTIATION OF SPLENOMEGALY—ASCOLI TREATMENT OF MALARIA

To the Editor—A white man aged 53 who has had an enlarged spleen for the past ten years has been examined by several competent internists and has had appropriate laboratory work up. The patient's medical history reveals the fact that in 1912 he lived in Tripoli at which time he was said to have had fever but diagnosis of the condition was not known. He had been in relatively good health until 1932 when he began to suffer from gastric distress and the spleen was found to be enlarged. Since then the spleen has been becoming larger. At the present time it is enlarged down to the iliac crest and is well beyond the umbilicus to the right. In the last two years the patient has had several attacks of severe pain in the left side of the abdomen. The pain was noticed first at movement, and these attacks have been presumably splenic infarction. The patient has been examined thoroughly several x-ray examinations of the chest and a gastrointestinal series proved negative. Urinalysis has been essentially negative. Complete blood counts revealed moderate anemia. Leukocytes have been normal in type and number and on no occasions have any basophils or parasites been found in blood smears. A splenic puncture done five years ago did not reveal any abnormality. The physical findings revealed the enlarged spleen mentioned and basal congestion in the left lower lobe. The patient has chronic rhinitis and a postnasal drip. The liver edge can just barely be felt. The blood Wassermann reaction was negative. Gastric washings have not revealed any tubercle bacilli. Gastric analyses have been within normal limits. Blood examinations including coagulation time, bleeding time, calcium and cholesterol determinations have been within normal limits. The diagnosis is presumed to be either splenic enlargement due to chronic malaria or possibly, kala-azar or leishmaniasis. The patient has been treated symptomatically by use of tonics and diet. He refuses an operation. The question arises of further treatment, the advisability of roentgen therapy or of the Ascoli treatment. If the Ascoli treatment is to be given what are the chances of epinephrine injections to be used causing embolic phenomena due to thrombi of spleen, which must have occurred?

O J. Pellitteri, M.D., New York

ANSWER—This letter implies a query as to diagnosis when it says that the diagnosis is presumed to be either splenic enlargement due to chronic malaria or possibly kala-azar or leishmaniasis. Kala-azar is the visceral form of leishmaniasis associated with enlargement of the spleen and liver. As in the case of chronic malaria, examination of material obtained by splenic puncture should serve to exclude malaria and kala-azar if the characteristic evidences of these diseases are absent. Even though there is a slight risk of hemorrhage after splenic puncture, it might be worth while to repeat this examination, since it has not been made for five years. The possibility that the symptoms have been caused by schistosomiasis seems improbable unless the patient lived for a long time in northern Africa in a region where he might have been exposed to repeated reinfection. Perhaps it would be worth while to consider again the possibility of this disease. If the three diseases mentioned are definitely excluded, a diagnosis of Banti's disease would seem to be probable, but histoplasmosis or some other form of fungous disease might be considered among the possibilities.

As to the direct question regarding the Ascoli treatment and its possible relationship to infarction of the spleen, in the first place infarction of the spleen is a common symptom of malaria, regardless of the use of epinephrine injections. The Ascoli treatment has been used by a considerable number of authorities. Froilano de Mello (*Experimental Studies on the Treatment of Malarial Splenomegalies by the Method of Ascoli*, *South African M J* 12:835 [Nov 26] 1938) published an excellent critical study of the subject and a general review. Many writers have reported groups of cases numbering from about 20 to 400. For the most part the reports fall into two groups: (1) those which are enthusiastic about the results of the treatment and (2) those which noted little or no benefit from its use. A number of authors stress the fact that transitory circulatory disturbances not infrequently result. These most commonly occur after a number of injections have been given. Giuseppe Pizzillo (*Malarial Splenomegaly and Venous Thrombosis Treated with Intravenous Epinephrine*, abstr. *Trop Dis Bull* 38:32 [Jan] 1941) reported failure to obtain reduction in the size of the spleen in a case which subsequently proved fatal. Toward the end of the course of treatment, after the twentieth injection, there was a copious hematemesis followed by abundant melena. Six months later splenectomy was performed and was followed by death. The author attributed the absence of contraction of the spleen after administration of epinephrine to phlebotic thrombosis, which he assumed to have existed prior to the treatment. Only a single published case found seems to have a direct bearing on the question (Jorge, A. Lourenço da Silva, Jose Ferreira, and Leal, A. Estillac, *Congestive Splenomegaly with Hemorrhage*, abstr. *Trop Dis Bull* 33:266 [April] 1936). These authors report a case diagnosed as Banti's disease in which administration of epinephrine brought about considerable reduction in the size of the spleen. Subsequent hematemesis was followed

by still further reduction. In this case it was thought that splenic thrombophlebitis had occurred and had been followed by rupture of veins of the gastrosplenic anastomoses. It does not seem necessary to suppose that use of epinephrine caused the thrombophlebitis or the hemorrhage. The fact that only 2 cases of thrombophlebitis which might conceivably be attributed to the use of epinephrine have been found would make it appear that the risk of such an eventuality is small.

WAR ACTIVITIES OF GIRL SCOUTS AND GIRL GUIDES

To the Editor—Please send me information as to the duties of the Girl Scouts in civilian emergency also information as to the English Girl Scouts activities
W J Tucker, MD Ashland, Wis

ANSWER—Girl Scouts have taken part in civilian emergency activities in their various localities, meeting the local needs and fitting into the local picture. The composite picture of service given by Girl Scouts throughout the country is as follows: Girl Scouts collected tons of paper and scrap metal in conservation drives, bottles and special materials for clinics, thousands of books for soldiers in camp, old clothes, first aid and invalids' equipment for the Red Cross. They made clothes and quilts for the Red Cross, Needlework Guild and other agencies, cookies and camp kits for soldiers, baby trays and toys for nurseries, bandages and card files for hospitals, surveys of available hospital space and possible emergency bed space, gardens to grow food and herbs needed by welfare groups for medicines and cakes and candy to raise money for relief agencies. They gave welcome to the children of defense workers and refugees help at home and in day nurseries to release mothers for other jobs, clerical help to social agencies, and gifts and friendship to old folks' homes, orphanages, veterans and other needy families and institutions. No one troop could do all these, but each did some. The older girls from 15 to 18 are organized in groups known as Senior Service Scouts and receive specialized training and give special service in first aid, child care, messenger service, emergency outdoor cooking and through the Wing Scouts, a newly organized group, make model airplanes and learn how to identify planes.

The Girl Guides of Great Britain have taken an active part in the war effort. These girls have participated in the usual salvage projects in various localities and also were asked by the air ministry to collect empty cotton spools, and collected over two hundred thousand of these. They have helped in harvesting and farming and have also assisted in camouflage projects in small communities and have made use of camouflage in concealing their own tents in their own small camps. They have helped in teaching "blitz cooking" for family, neighborhood and large canteen groups using improvised fireplaces made from bricks from bombed houses. At the request of the Ministry of Food demonstrations of this emergency outdoor cooking were given throughout the British Isles.

FLOATING OPACITIES OF EYES

To the Editor—A white man aged 46 whose previous history is irrelevant has complained for the past twenty years of seeing small objects floating in front of his eyes particularly in front of the left eye. He claims that they are small capillaries in which he can distinctly make out red blood corpuscles. Sometimes they are near to his vision and sometimes they seem distant. Together with this he has headaches mostly over the left fronto-parietal region which are more intense when he is trying to concentrate on his work. His vision is 20/20 in both eyes without glasses. His urine and blood study (Wassermann blood count and study of blood smear) are negative. Many ophthalmologists have seen him some called it avitaminosis while others said it was vitreous bodies floating about the eye chambers. None have however been able to give him any relief. He is a sign maker making both neon and painted signs.

Peter J. Milazzo MD Corona L I N Y

ANSWER—The query does not state whether the floating opacities are actually visible in the vitreous of the patient. If none are visible, the condition is a type of subjective scotoma for which no organic basis has been found. It may be compared to certain tactile sensations without organic cause. It indicates no pathologic condition of the eye and does not really interfere with vision except as an annoyance. Correction of refractive errors, if present, and attention to other possible causes of nervous exhaustion are sometimes of value. The symptom usually becomes much less noticeable and eventually may disappear or be noticed only under exceptional conditions. No relation with avitaminosis is known to exist.

If visible vitreous opacities are present, uveitis must be excluded, but vitreous opacities also occur as part of a presenile degeneration of the vitreous which is common and seldom has any serious consequences.

EGG WHITE IN TREATMENT OF CANCER

To the Editor—There appeared in the New York Times of Dec 2 1942 an article entitled 'Egg Whites Tested as Cancer Relief'. I have a patient with carcinoma of the bladder who has been operated on and irradiated at a large clinic. His prognosis as we all know is hopeless with a gradual decline day by day. Yesterday his wife came to my office with the article mentioned and asked if there was anything in it that would give her husband any relief or comfort. I advised her that as far as I knew there was nothing in this treatment, but, to ease her mind, will you kindly tell me the merits of the article or of the treatment?

M D, New York

ANSWER—The theoretical basis for the use of egg white in the treatment of cancer depends on five observations:

1. The biotin content of some tumor tissue was found to be greater than that of normal tissue of the same origin.
2. Temporary regressions of new growth have been reported rarely to follow intercurrent infections.
3. Certain infectious agents, particularly bacteria, are known to use biotin in their metabolism.
4. Biotin has been found to have a weak effect in inhibiting the protective effect by certain dietary constituents against liver cancer caused in the rat by the administration of dimethylaminoazobenzene.

5. A protein known as avidin, contained in egg white may combine with and inactivate biotin.

The feeding of egg white to small animals induces a biotin deficiency. Wogom fed mice with cancer sufficient avidin to eliminate biotin effect in their bodies completely. Even during this period new metastases appeared. There is no reason to suppose from the evidence available that the feeding of egg white or its protein constituent, avidin, to man or animals will cause any change in the course of a neoplastic growth. The single exception to this statement is the report by Kaplan recently discussed before the Radiological Society of North America. No confirmations of Kaplan's observations have been published.

SHOCK VERSUS INFECTION IN TREATMENT OF COMPOUND FRACTURE

To the Editor—There is some question in my mind regarding the early treatment of compound fractures. I know the Orr-Trueta technic and feel that I can apply this method when given the proper instruments and hospital. However, it is the early treatment that offers somewhat of a puzzle. Let us assume that our patient is a soldier on the battlefield. His wound is a compound fracture with a protruding bone. The area around the fracture is quite dirty, and perhaps there is a piece of shell and cloth within the wound. An aid man or litter group equipped with splints encountered him. Now should the wound be simply covered with a sterile dressing and the patient gently placed on a litter with some support like a pillow or coat or should traction and splints be applied regardless of whether the protruding bone might be drawn into the wound? This phase of treatment has troubled me no end. I have felt that it might be wise to place about 10 Gm of sulfanilamide in the wound apply traction and splints and send the patient on to a hospital if possible where proper treatment can be given. Shall we sacrifice shock prevention by no immobilization and thus tend to prevent infection or shall we avoid shock and gamble an infection by immobilization? It must be one or the other. I myself should rather place sulfanilamide in the wound apply splints and avoid shock.

M D Massachusetts

ANSWER—The conclusion that it is better to avoid shock and gamble on infection by immobilization in fixed traction in a Thomas leg splint, even if bone fragments are drawn back into the wound, is correct and orthodox. Thus treated not only is shock lessened but pain, possible hemorrhage and avoidable motion at the fracture site leading to clumping of the tissues by bone fragments may be eliminated. The sulfanilamide if obtainable, is highly desirable to spread into the wound, which is covered with a sterile dressing.

BASAL METABOLISM IN NERVOUS PATIENT

To the Editor—Will the administration of a small amount of sodium bromide or of phenobarbital to an apprehensive patient for sedative purposes shortly before a basal metabolic determination affect the results undesirably? The patient I have in mind has no conclusive signs or symptoms of hyperthyroidism.

M D Colorado

ANSWER—The administration of a small dose of sodium bromide or of phenobarbital probably will not have much effect on the basal metabolism readings of the patient described. The best way to get a good reading of an apprehensive patient is by frequent determinations of the basal metabolism on different days. In fact, little attention should be paid to a single test of any patient. The important observation is the level of metabolism.

DIETARY CONDITIONS IN INDUSTRY

ROBERT GOODHART, M.D.

FOREST HILLS, N. Y.

The proper feeding of large groups of people is a complicated task involving the consideration of many factors and the cooperation of both private and governmental agencies. There are the problems of provision of nutritious foodstuffs, of the distribution, preparation and service of foods, of food habits and of adequate housing, transportation and feeding facilities, and there is the question of cost and purchasing power.

The job we have set for ourselves, that is, improving the quality of the meals consumed by the industrial worker (and thereby improving his health and morale), not only demands the consideration of these problems but poses a few others more or less peculiar in themselves. These include:

1 The dinner pail or lunch box. The great majority of industrial workers have their lunches prepared for them at home, while others patronize local merchants who prepare lunch boxes for this purpose. This will probably continue to be so, although the time required to inspect all packages coming in and going out of industrial plants engaged in war work has, in some instances, discouraged this practice.

2 The restaurants, lunch wagons, refreshment stands and food hawkers located in the vicinity of industrial plants.

3 The rolling kitchens or food carts, refreshment stands and automatic vending machines employed within plants.

I do not mean to imply that these devices are to be condemned, quite the contrary. A problem does arise however, in relation to the types of foods obtained from them by the workers. Too often they function largely as vendors of foods of very limited nutritional value, e.g. candy, pastry and soft drinks.

Assuredly, a situation which appears to encourage some of our industrial executives to make statements for publication and general dissemination like the quotations which follow calls for, at the very least, an active educational campaign.

"It is our firm belief that the candy bars sold throughout the plant are a definite aid to the health and efficiency of our employees."

"Candy is important in lessening fatigue and increasing morale of employees."

"Employees' nourishment afforded by candy dispensed through canteen."

4 The preparation, service and cost of midshift meals provided by restaurants and canteens located on plant premises.

5 The disruption of the eating habits of great numbers of workers which resulted from the institution of the twenty-four hour working day.

6 The optimal length of the lunch period and of the interval between feedings.

7 The decision as to what proportion of the worker's daily nutritive requirements must be provided for at the plant if he is to be kept well nourished and in good health. Many workers come to work without breakfast, particularly when distances are great and transportation facilities poor. In other instances, the community facilities are grossly inadequate to provide for the proper feeding of the new workers brought into the community by war industries. The Committee on Nutrition in Industry of the Food and Nutrition Board of the National Research Council has recommended that the midshift meal should supply at least one third of the worker's daily food requirements and has suggested that it would be desirable for at least two thirds of the daily requirements to be supplied at the plant.¹ The British government has stipulated that factory canteens in Great Britain should supply the workers with two thirds of their daily nutritional needs.

8 The particular dietary requirements of workers who must come into contact with toxic chemicals and other noxious agents, or who labor under unusual conditions of physiologic stress.

There are other questions, which I am sure have already occurred to many, that must be answered for individual plants and industries.

It is not possible for me to discuss adequately the whole problem of industrial feeding in the short time allotted to me. I shall therefore restrict myself largely to demonstrating that a problem of nutrition exists among industrial workers by citing the conditions found in a few representative industrial cafeterias by several independent investigators.

In March 1942 Miss G. Dorothy Williams of the New York State Nutrition Committee inspected the cafeteria of a large plant located near Albany, N. Y. She found that the men's trays contained mostly meat, potato, bread, pie and milk, while the girls consumed sandwiches, coffee and pie. There were few trays with a vegetable or salad. This may have been due partly to the fact that the vegetables looked rather unpalatable, because of too long periods of soaking and overcooking. The salads were also quite unattractive, because of either poor refrigeration or poor management. Practically no whole wheat breads or rolls were sold.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J. June 12, 1942.

1 The Food and Nutrition of Industrial Workers in Wartime. National Research Council. Reprint and Circular Series no. 110. April 1942.

Miss M M Queneau and Dr S A Hyman of the New York State Health Department are at present conducting surveys of foods served and consumed in several New York State factories. They have furnished me with their observations on the three plants at which their studies have been completed. In the first plant they found that only 24 per cent of the workers ate a good lunch and 26 per cent ate a poor lunch, in spite of the fact that a liberal choice of protective foods was offered. In the second plant only 12 per cent of the workers had good lunches, and those of 41 per cent were poor. The third factory

of foods offered to the employees. I found that it was possible to choose a satisfactory lunch. However, on both occasions my lunch was priced by the cafeteria manager at 57 cents. The average sum spent for lunch in that cafeteria by the employees is 37 cents. Between 200 and 250 of the 500 employees eating in the cafeteria regularly choose the dry's "special," which is priced at 30 cents. Coffee is included but milk is 5 cents extra. It is not surprising, therefore, that on the two occasions that I witnessed the lunches coming off the cafeteria line not more than 100 employees chose milk with their meals. In another plant which I visited the manage-

offered a very limited choice of foods, and none of the factory workers obtained a good lunch, while the lunches of 77 per cent were classified as poor.

As criteria for evaluating the lunches, Miss Queneau and Dr Hyman used the following:

Good if lunch included all three of the following items: milk, fruit or vegetable and a main dish—meat or fish.

Fair if lacking one of these three items.

Poor if lacking two or all of the three items.

It is obvious that a lunch could meet all three of these criteria and still be grossly inadequate.

Due consideration must be given to the economic factor involved in the choice of lunches by factory and office workers. Last month I had an opportunity to inspect the cafeteria of a factory in Brooklyn. On two different occasions I selected lunches from the choice

ment was keenly disappointed with the response of the employees to its innovation of providing milk and orange juice at the main refreshment stand. I dare say that a possible answer to the problem of the poor consumption of these foods existed in the fact that a pint of milk cost 10 cents (one-half pints were not available) and a container of orange juice was 8 cents. Soft drinks and coffee sold for 5 cents each and remained the most popular drinks on the menu.

The Hartford Nutrition Committee, using standards similar to those employed by Miss Queneau and Dr Hyman, obtained like results in a survey conducted in two Connecticut plants.¹

On my tour of industrial concerns during the summer of 1941 I found that in almost every instance at least one half of the workers selected poorly balanced lunches even when a good choice was available.

As it is impossible in many large plants for the employees to go to lunch rooms for their noon meals in the short time allotted to them for this purpose (twenty to thirty minutes as a rule), food carts are often sent into the factories. Some of these carts make provision for one hot dish. However, many do not, and all of them are well stocked with foods of doubtful nutritional value e g sandwiches, pastry, candy, soft drinks and coffee, in addition to milk and ice cream.

During my survey of dietary conditions in industry last summer I found that from 10 to 25 per cent of the employees of thirty-three large plants visited consumed milk at the plant. My experiences since that time have not made me feel inclined to doubt the applicability of this estimate to industry as a whole. In 1936 the National Dairy Council reported² that "it appears that there is no uniformity in the practice (between-meal milk service), ranging from almost no such service in some localities to a 90 per cent coverage in others. In the main, our inquiries indicate that between-meal milk is now supplied in a few factories in most localities but that there is almost no such milk service in offices. Furthermore it appears that employees do not invariably buy milk when it is made available to them. The percentage of workers taking milk varies with such factors as food habits of particular races, the season of the year and the age and sex of the workers. Sometimes as few as 2 per cent buy the milk, and rarely more than 40 per cent take it regularly."

These findings indicate a need for an active and intensive educational program. Not only is there a need for the dietary education of the worker and his family, but just as imperative is the need for the dissemination of correct information among cafeteria managers and plant executives. A great deal can be accomplished in increasing the consumption of foods and meals of high nutritional value and in decreasing the consumption of relatively poor foods by the application, by food vendors, of modern merchandising methods toward this end.

Any campaign to convince the workers of the desirability of selecting proper meals at plant food dispensaries must be predicated on an assurance that the recommended foods possess the nutritive qualities attributed to them. Unfortunately altogether too frequently it is impossible to give such assurance.

Through the cooperation of the Crotty Corporation we were able to obtain a few assays on the meals served by an industrial cafeteria to employees of a war industry in the New York area. We selected the meals for assay from the cafeteria line at the time the company employees were being fed. The various constituents of the meals were weighed in the kitchen, placed in containers with dry ice and taken to the laboratories where assays were started immediately. The assays of the diets described in tables 1 and 2 were performed by the Fleischmann Laboratories, under the direction of Dr C N Frey.

The thiamine determinations were made by the fermentation method, sulfite corrected, of Schultz, Atkins and Frey. The content of riboflavin and of niacin was determined by the collaborated methods of the Research Corporation and ascorbic acid by the indophenol method.

It is the custom in this cafeteria to serve a "daily special" for 30 cents. As a rule, more than 200 of

the 500 employees patronizing the cafeteria select the "daily special." Table 1 summarizes my findings on the "special" provided on April 29, 1942. The vitamin content of the meal, as estimated from published data on the nutritive values of the raw foods,³ is sufficient to supply considerably more than one third of the daily requirements⁴ of a moderately active man of 154 pounds (69.9 Kg) except for ascorbic acid, for which the figure represents barely one third of the requirement and for vitamin A.

However, assay of the meal, after preparation and service, discloses a thiamine content of only 0.073 mg representing a loss of approximately 92 per cent of the thiamine content of the fresh raw food. Only 4.3 mg of ascorbic acid was recovered, representing a loss of 82 per cent. The meal as served therefore supplied only 4.1 per cent of the daily requirements for thiamine and only 5.7 per cent of the ascorbic acid needed by a moderately active man.

The riboflavin content of the foods proved quite stable to the method of preparation used. The niacin, protein and calory content proved to be satisfactory. The riboflavin and niacin content of the other meals tested also proved satisfactory.

TABLE 3—Recipe for Lamb Stew

Boned shoulder of lamb	3 pounds 9 ounces
Potatoes	2 pounds
Onions	10 ounces
Celery	6 ounces
Carrots	27 ounces
Flour	1.5 ounces*

TABLE 4—Recipe for Raw Vegetable Salad

Chopped cabbage	12 ounces
Chopped green peppers	5 ounces
Chopped radishes	3 ounces
Grated carrots	6 ounces
Vinegar	¾ cup
Salt	1 teaspoon
Sugar	2½ teaspoons*

The estimated content of vitamin A is only 26.8 per cent of the recommended daily requirement—a definitely low figure, particularly since most of the vitamin A was present as carotene.

Table 2 represents an attempt by me to select a nutritious meal from the varieties of food offered by the cafeteria to its patrons. It would appear that I was reasonably successful, although the price of the meal proved to be 20 cents higher than the average sum spent by the plant's employees for their lunches.

Here again the preparation and service of the meal was accompanied by a loss of thiamine hydrochloride (52 per cent) and of ascorbic acid. The ascorbic acid actually found in the meal is practically all accounted for by the tomato juice present.

The relatively high "found value" of riboflavin as compared to the estimated value is explained by the fact that no estimate was made of the vitamin content of the custard pudding.

This seems an appropriate place to draw attention to the fact that 87 per cent of the thiamine content of the "daily special" described in table 1 was provided by the meat, potatoes and beans, a condition associated

³ Sherman, H. C. *Chemistry of Food and Nutrition*, ed. 6. New York: Macmillan Company, 1941.

⁴ Recommended Allowances for Various Dietary Essentials. Committee on Food and Nutrition, National Research Council. *J. Am. Dietet. A.* 17: 565 (June/July) 1941.

with a 92 per cent loss of thiamine hydrochloride in the preparation of the meal. The meat, potatoes and carrots provided 40 per cent of the thiamine content of the second meal, which showed a loss of 52 per cent of the total thiamine content in preparation.

In order to check on the destruction of thiamine hydrochloride in low cost meat dishes, Miss Marie Casteen, research associate in home economics at Teachers College, Columbia University, prepared a lamb stew according to the recipe given in table 3.

This stew was eaten by a number of people and pronounced excellent as far as taste acceptability was concerned. The recipe yielded 136 ounces of stew, about seventeen 8 ounce portions. The theoretical thiamine content of each 8 ounce serving was 0.384 mg., while assay by the fermentation method, with sulfite correction, gave a value of 0.135 mg., representing a loss in preparation of approximately 65 per cent.

Miss Casteen also prepared a raw vegetable salad according to the recipe (table 4).

Three and one-half hours after preparation this salad was assayed for ascorbic acid and found to contain

The assays in this case were run by the Laboratory of Industrial Hygiene. Thiamine determinations were by the fermentation method with sulfite modifications, riboflavin determinations by the method of Snell and Strong, niacin determinations by the methods of Dann and Handler and vitamin C determinations by the Stevens method.

The results of analyses of this meal show a much better retention of vitamin content and indicate that with proper selection and proper handling good food can be delivered without excessive vitamin loss.

My associates and I realize the inadequacy of our sampling as a basis for any generalizations, and our studies are continuing. However, the cafeteria from which the diets were selected does not differ in any important respect as to management, equipment, menus and the purchase and preparation of foods from many other "better type" industrial cafeterias which we have visited. It is well known to nutritionists and research workers in the field of nutrition that of all the vitamins, thiamine hydrochloride and ascorbic acid are the most liable to destruction in the preparation and cooking of

TABLE 5—*Forty Cent Daily Special May 28 1942*
(Corrected to Improve Vitamin Content)

Percentage lost in preparation			No data	50	0	No data

5.35 mg. per ounce. Although this amount represents about 40 per cent less than the theoretical content, it is still appreciable, being in the range of values found for canned tomato juice.

In view of the satisfactory content of this salad after a lapse of time sufficient to allow for normal handling in a cafeteria, the subject was discussed with the operators of the cafeteria and plans were made to serve a slightly changed "daily special." This special was based on the one described in table 1. The braised breast of lamb was seasoned by means of a commercial brewers' yeast extract. The potato item was served as a boiled whole potato rather than as mashed potatoes. The ordinary white bread was replaced by enriched bread, and the beverage was milk instead of coffee. The raw vegetable salad was added. The meal was prepared in the kitchen of the cafeteria and selected from the service counter in the same manner as the food first tested. The cost of the meal was 40 cents, an increase of 10 cents over the former "daily special."

The makeup of the meal, together with the estimated vitamin content and the results of assays, is shown in table 5. The theoretical vitamin values used in this table were computed from the same source as those in tables 1 and 2. The value for the added brewers' yeast extract was based on previous assays of the material

foods. Riboflavin is relatively stable to heat, although it is destroyed to an appreciable extent in alkaline solutions at temperatures above 212 F.⁵

Not only do the results of these assays demonstrate the ease with which the recommended daily requirements of the Food and Nutrition Board of the National Research Council can be met by the proper selection and preparation of foods, but also they illustrate the conservatism of the recommendation by the Committee on Nutrition in Industry of the council that meals served in the plant should supply at least one third of the daily requirements.

Those who question the necessity or desirability of adhering to the recommendations of the Food and Nutrition Board are advised to read the recent article by Williams and his associates on induced thiamine deficiency in man.⁶ The data of these workers indicate that, for their subjects, the optimal daily intake of thiamine hydrochloride was not less than 0.5 mg. or more than 1 mg. for each 1,000 calories of their diet.

They also found that, when subjects were maintained on daily intakes of 0.22 mg. of thiamine hydrochloride

6. Williams R. D., Mason H. I., Smith, B. F. and Wilder R. M. Induced Thiamine (Vitamin B₁) Deficiency and the Thiamine Requirement of Man. *Arch. Int. Med.* 69: 721 (May) 1942.

per thousand calories of the diet, gross changes of behavior occurred, including a "diminished inclination to perform accustomed tasks and progressive decrease of ability to make social adjustments within the group." The more active subjects were the first affected. In the words of the authors, "They did not maintain good health. On the contrary, they all suffered impairment of physical and mental efficiency, with manifest evidence of biochemical abnormalities. They lived on a plane of vitality lowered by a deficiency of thiamine, a plane which could be raised again only by the administration of thiamine."

During the past year the Committee on Nutrition in Industry of the National Research Council has been sponsoring a study of the nutritional status of industrial workers. This study is being conducted under the direction of Dr. Henry Borsook. To date, slightly more than 1,000 men have been examined, with some extremely interesting results.

Forty-two per cent had plasma ascorbic acid levels of less than 0.5 mg per hundred cubic centimeters (17 per cent less than 0.25 mg). Nineteen per cent showed signs of premature degeneration of the nervous system, as evidenced by loss of vibratory sensation in the toes to a C 256 tuning fork (generally accepted as pathologic in men under 35 years of age). Forty-seven per cent presented gross vitamin A deficiency as evidenced by localized elevated conjunctival spots. Twenty-eight and six-tenths per cent had a blood hemoglobin content of less than 14 Gm per hundred cubic centimeters.

As pointed out previously in this paper, the proper feeding of industrial workers is a complicated problem the solution of which requires the cooperation of industry, labor, the community and the government. My own observations have impressed me with the progress being made toward the integration of the efforts of these various groups so that each one's talents and opportunities for work can be most efficiently utilized. However, the evidence is so convincing that the nutritional status of large numbers of our industrial workers is below a level compatible with optimal health and physical and mental efficiency that a decided acceleration in the rate at which remedial procedures are being instituted throughout the country is indicated.

98-50 Sixty-Seventh Avenue

ABSTRACT OF DISCUSSION

DR. NORMAN H. JOLLIFFE, New York. I think this paper indicates why dietary surveys, though indicating a high degree of dietary inadequacies in all population groups surveyed, are apt to underestimate the prevalence of poor diets. I wish to emphasize that the vitamin losses of cooked foods are confined almost exclusively to ascorbic acid and thiamine. I have recommended in calculation of diets that the vitamin C value content of cooked foods other than tomatoes should be estimated as zero and that the thiamine content of cooked foods be estimated as 50 per cent of the raw value. These studies by Dr. Goodhart confirm the general applicability of this rule. The only dependable dietary sources of vitamin C are citrus fruits, cooked or raw tomatoes, and fresh raw fruits and vegetables. Three other points made by Dr. Goodhart I wish to emphasize. First, the necessity for industry to employ a dietitian or nutritionist to supervise the cafeterias to insure at least a third and preferably a half of the nutritive essentials in the noon day meal. Second, that the cafeterias and the serving of food in industrial plants should be on a nonprofit basis or even subsidized by management or government. Third, that the responsibility for adequate meals be placed in the hands of the medical department.

SKI INJURIES

A STATISTICAL AND ANALYTIC STUDY

JOHN R. MORITZ, M.D.

SUN VALLEY, IDAHO

It is my purpose in this paper to review and briefly analyze all the reported injuries sustained as a result of skiing at Sun Valley for a three year period ended in May 1942. This is now a pertinent subject in view of the increased interest and participation in skiing. Considering the fact that the United States Army is engaged in the training of ski troops, there is additional practical interest in the type of injury which may be anticipated.

Owing to the isolation of Sun Valley, almost all casualties must, from necessity, pass through one of several medical offices. All the medical facilities are under one head, and a single record system is observed.

TABLE 1—Summary of Ski Injuries

	Number
Bones fractured	257
Dislocations	35
Sprains and strains	762
Contusions	147
Abrasions	57

Fibula avulsion of distal tip	7
Astragalus posterior process (os trigonum)	4
Astragalus avulsion	3
Scaphoid avulsion	1
Metatarsal shaft	4
Metatarsal sesamoid bone	1

This situation makes for a high degree of statistical accuracy. A full time, paid ski patrol is present at all times on the various slopes. It is the duty of the patrol to observe the factors contributing to cause accident as well as to administer first aid and transport the casualty to the medical department. The contributing factors have been previously discussed by Brothers¹ and will not be considered further in this paper.

Table 1 is a general classification of all injuries seen. It will be noted that over 20 per cent of the total is represented by either fracture or dislocation. Sprains and strains account for more than 50 per cent but the fact that the average period of disability for this injury was about four days indicates that many of them were very minor.

Table 2 lists one hundred and eighty-seven fractures involving the bones of the lower extremities. In all but twelve of these the force applied was one of torsion. It may appear dogmatic to describe a single force responsible for fracture, but it has been observed that ski injuries occur in a rather singular manner. At the time of fall, the knees usually are slightly flexed. The ski becomes a fixed object which fixes the foot. The fall

is to the side and forward. Thus, torsion strain is exerted through external rotation. It is my opinion that there is no weight bearing at the time of injury.

The femur was fractured three times. Twice the force was a direct impact. Only one fracture of this bone occurred as a result of torsion strain. This is rather contradictory to the general impression that the

combination of forces—torsion, abduction and weight bearing. Although the posterior malleolus of the tibia was fractured as a result of direct impact three times, the os calcis was never fractured. The fracture of the posterior process of the astragalus (os trigonum) occurred once following direct impact and three times following severe torsion strain.

It will be noted that more than half of the fractures seen are those usually referred to as "ski fractures." This is a spiral fracture involving the distal shaft or the distal head of the fibula. It occurs as frequently in one leg as in the other. The mechanism is external rotation without weight bearing. The force approaches true torsion as nearly as possible. In the consideration of this particular injury there are more important factors than the fracture itself. Rupture of the tibiofibular ligament may occur with slight lateral displacements of the astragalus. In over 10 per cent of the series this

TABLE 3—Fractures of Tibia

Fracture posterior malleolus	1
Fracture of internal malleolus	1
Bimalleolar fractures	2
Trimalleolar fractures	2

incidence of femoral fracture in torsion-strain injuries is greater. One of every five fractures was a spiral fracture of the tibia. The line of fracture in every instance involved one third or more of the entire tibial shaft and occurred in the middle and distal thirds. Usually the proximal shaft of the fibula also was fractured, and on one occasion the fibula was fractured in the proximal and distal shaft leaving this bone in three separate segments. The spiral fractures of the tibia are usually comminuted.

Six injuries were seen in which the only fracture was of the proximal shaft of the fibula. This fracture first described by Maisonneuve,² is of some academic interest. Ashhurst³ considered the fracture the result of external rotation of the foot so as to produce first a tibiofibular diastasis. He thought that the continued application of the torsion force finally produced fracture of the proximal shaft of the fibula. Hoenigschmied,⁴ in cadaver experiments, found evidence to support this conception. An attempt was made to demonstrate tibiofibular diastasis in the present series but it was not possible to do so. The relatively rapid recovery of the ankle sprain in these cases also leads me to believe that diastasis did not exist. It is reasonable to believe that the law of inertia is a factor in the relationship between the fracture force and the fracture itself. Certainly the objective evidence of a given force varies with the time consumed by the application of the force. In this particular type of fracture the snow conditions were usually

uniform, being sticky and heavy. Although there were but six fractures of this type in three years, two of them occurred within the same hour. The force of torsion was quickly applied in each instance.

The trimalleolar and bimalleolar fractures reported are typical of those seen so frequently when there is a

	Number
Sprain of internal lateral ligaments (to occur with sprains of ankle)	21
Conusion of cartilage	7
Dislocation of patella	2
No fractures of anterior tibial spine	
Three known cases of Tieg's ligament dislocation reported following injury to the internal lateral ligament	

could be clearly demonstrated. Failure to recognize this, with the consequent error in proper treatment, will account for considerable disability.

Table 4 is of interest in revealing the relative frequency of the various types of injury to the ankle. Considering the fact that the sprain group represents many very minor injuries, the incidence of fracture is high. All severe sprains are submitted to x-ray examination, and we have been acutely critical in each instance of the presence of injury to the tibiofibular ligaments. Laceration of this important structure was clearly demonstrable in 8 instances associated with sprain.

Carothers⁵ observed in a limited number of experiments on fresh cadavers that it was necessary to divide the anterior, middle and inferior bands of the external lateral ligaments in order to produce astragalal displacement. Although there was displacement in 15 cases, the injury allowing the displacement was thought to be due to tibiofibular ligament laceration, with or without fracture of the fibula, rather than to injury to the external lateral ligaments. This is logical in view of the fact that the injuring force is one of torsion primarily.

² Maisonneuve Arch. gen. de med. 1 165, 433, 1840.
³ Ashhurst A. P. C., and Bromer R. S. Classification and Mechanism of Fractures of the Leg Bones Involving the Ankle Arch. Surg. 4 51 (Jan.) 1922.
⁴ Hoenigschmied Deutsche Ztschr. f. Chir. 8 239 1877.

⁵ Carothers R. G. Ann. Surg. 115 654 (April) 1942.

Two methods of determining diastasis have been employed. One, suggested by Bromer,⁴ is predicated on a true anteroposterior roentgenogram in which the shadow of the anterior lateral tubercle of the tibia must normally overlie at least one half of the fibular shadow. The second, suggested by Murray,⁵ requires light anesthesia so that the injured ankle may be manipulated under fluoroscopic vision. External rotation of the foot, when there is tibiofibular ligament laceration, will allow the fibula to wing out away from the tibia.

It will be noted from table 5 that injuries to the foot were relatively infrequent. The sprains resulted in very short periods of disability. Periosteal tears were demonstrated four times: once from the anterior surface of the scaphoid and three times from the anterior surface of the astragalus. Fractures of all but the first of the metatarsal bones occurred.

Second only to the ankle, the knee was most frequently injured. Table 6 shows that the internal lateral ligaments were sprained 261 times. One fourth of these occurred in conjunction with ankle sprain. In this group the major injury, subjectively, is usually the knee

TABLE 7—Injuries to Upper Extremities

Dislocation of fingers	3
Dislocation of nose	1

It has been pointed out that an ankle sprain may be so severe as to distract the examiner from a fracture of the proximal shaft of the fibula. It is also possible for the pain experienced from sprain of the internal ligaments of the knee to make the patient minimize a fracture of the distal head of the fibula.

Localization of pain in the tibial insertion of these ligaments may be demonstrated always. That avulsion of the femoral attachment occurs occasionally is certain. In 3 instances calcification could subsequently be demonstrated by x-ray examination. Appreciation of the pain and disability associated with this unpleasant complication makes the need for careful x-ray examination of the knee following injury obvious.

It is of considerable interest that contusion of the cartilage was diagnosed in only 7 instances. External rotation of the lower leg is associated with movement of the internal semilunar cartilage laterally, so as to approach more intimately the weight bearing surfaces. However, rotation or torsion strain alone is rarely sufficient to produce serious injury to the cartilage. It must be accompanied by weight bearing. In ski injuries these two forces are infrequently applied at one time.

Table 7 lists the injuries seen to the upper extremities. These are of little specific interest in reference to

skiing, since they are the result of impact. Fracture of the greater tuberosity of the humerus occurred eleven times. There was no displacement of the fragment. In 2 instances this fracture was associated with dislocation.

Tables 8, 9 and 10 are included to make the report complete. In these groups there is nothing distinc-

tive from the injuries associated with other contact sports. The incidence of these injuries will vary greatly with terrain and the type of skiing done.

In returning to table 1, it is noted that approximately 75 per cent of the ski injuries reported are the result of torsion strain. Translated into terms of disability, this represents over 90 per cent. Consequently, any modification of skiing which will tend to decrease the application of torsion strain to the leg will reduce the number of injuries which are now being sustained. A review of the evolution of ski equipment shows that there has been a progressive tendency to approach a state in which the foot and ski act as a unit. The only noteworthy motion of the foot on the ski is a hingelike action of a few degrees. When the ski point becomes fixed in heavy snow, the foot also becomes fixed. Consequently the weight of the body going forward makes it necessary for something to give, and it is usually the lower extremity. This development in the type of ski binding now used has made for greater skill in racing and greater control in making turns and has permitted the perfection of a new style of skiing. However, there can be no question that it has been responsible for an increase in the number of torsion-strain injuries. To return to a "safe" binding which would allow the foot to become disengaged from the ski when severe torsion strain is applied would reduce this group of injuries to

TABLE 10—Miscellaneous Injuries

a minimum. Such a suggestion will never be accepted by those who ski for the thrill of accomplishing the most that can be obtained from the sport and who are willing to pay the price of injury and disability when it comes.

However, when skiing is studied as a means of transportation, as is the case when the mountain troops are concerned in the United States Army, a severely sprained ankle or a fractured leg is of considerable practical importance.

THE PHYSICALLY HANDICAPPED IN INDUSTRIAL ESTABLISHMENTS OF THE GOVERNMENT

POSSIBILITIES FOR THEIR INCREASED PLACEMENT

VERNE K. HARVEY, M.D.

Medical Director U. S. Civil Service Commission

AND

E. PARKER LUONGO, M.D.

Assistant to Medical Director U. S. Civil Service Commission

WASHINGTON, D. C.

Under the necessity of compensating for wartime manpower shortages, the U. S. Civil Service Commission, central recruiting agency of the federal government, has conducted studies which show that thousands of jobs in industrial establishments of the government such as arsenals and navy yards can be filled by judicious placement of physically handicapped persons.

A valuable source of manpower is thus opened up because many of the jobs considered in the studies have thus far been open only to persons with all their faculties.

Out of the effort to determine what positions in the federal service may be filled by physically handicapped persons and to encourage federal appointing officers to appoint these persons when practicable, in their respective agencies a medical function of major proportions has developed. It is being performed by the commission's medical division as a special aspect of the regular function of devising minimum physical requirements for positions in the federal service.

The major outcome of the medical division's effort to promote the utilization of the services of the physically handicapped whenever possible will be the issuance of a manual, which will make available to all persons engaged in placement, training and recruitment activity for the federal civil service information with respect to positions which are suitable for the various types of physical handicaps and where these positions are located. It is expected that the first edition of the operating manual will include more than fifteen hundred positions, representing many thousands of individual jobs, additional positions which, in the opinion of the regional medical officers or Vocational Rehabilitation Services, offer placement potentialities for the physically handicapped will be investigated and if appropriate from the standpoint of placement will be added to those already included in the manual.

Placement of the physically handicapped can be effected with a minimum loss of efficiency and a minimum industrial risk provided there is—

1. Proper evaluation of physical requirements of the positions as determined by job analysis of physical fitness factors.
2. Proper coordination of training, recruitment and placement programs.
3. A genuine interest in "selling" the applicant's qualifications to the employer.
4. Proper coordination between the medical service of the commission, which is the recruiting agency for the federal government and the appointing officials of the operating agencies or their medical and safety advisers.

Since there are wide variations in environmental working conditions and in functional factors of the same job in different localities, the commission does not attempt to lay down definite overall rules establishing standards for placement. Instead it recommends individual consideration of each case.

The term "physically handicapped" is interpreted as meaning "any physical deficiency, peculiarity or impairment which presents a problem in placement."¹ This interpretation by implication projects environmental and functional factors of the position in question into the meaning of the term. For example, a one armed person with a history of tuberculosis is physically handicapped only as far as he is unable to operate certain types of machinery or to work under certain environmental conditions. The elements of function and environment (industrial physiology) become of prime importance in considering the physical defects of handicapped persons in connection with placement.

Restrictions placed on employment of the handicapped which are not justifiable on a functional, environmental or industrial risk basis are artificial in the view of the commission. Such restrictions, in view of the large number of qualified handicapped persons the majority of whom could be placed in some type of employment, are not reasonable—especially in wartime when there is a dearth of the supply of physically fit manpower in the civilian labor market. It has been conservatively estimated that there are between 2,500,000 and 3,000,000 persons in the United States with physical limitations of sufficient severity to become a factor in occupational adjustment.

Realizing that the success of its endeavor to utilize the services of the physically handicapped in the federal civil service depends on close cooperation between the recruitment, training and placement agencies, the commission has approved the establishment of a joint committee representing the commission, the Vocational Rehabilitation Division Office of Education, and the Council of Personnel Administration, which formulates to a considerable degree personnel policies for the federal civil service. This permanent central committee acts as a clearing and advisory group to organize more direct relationships in recruiting, training and placement activities.

In order that a proper evaluation of physical requirements of positions might be arrived at extensive surveys pertaining to more than two thousand positions are being conducted in sixty industrial establishments of the federal government, including navy yards, naval establishments, arsenals and several plants in private industry holding government contracts. The surveys were conducted by medical officers stationed in the thirteen civil service regions. In addition to direct observation of employees performing their duties, the surveys included consultation with foremen and supervisors who were familiar with all phases of the duties performed. The resulting information is now in the process of being coded according to the system of job classification established by the U. S. Employment Service Job Classification Code² and according to the disability placement classification devised by the commission. The information will be incorporated into a manual to be used by the commission's representatives in recruitment, by the training agencies and by the employing officers.

The manual will be in loose-leaf form and subject to modifications from time to time. Through it information which will be valuable in training programs can be made available to training agencies. It will keep

1. Placement of Physically Handicapped Applicants Through Public Employment Offices. State Operations Bulletin 10, pt. VII, Washington, D. C. Bureau of Employment Security, Federal Security Agency.

2. An occupational dictionary used wherever the description of a job showed it to be identical with or closely akin to the job surveyed.

the training agencies currently informed on placement potentialities in federal governmental industry. The information, correlated with information on current employment needs, especially with respect to positions in critical categories, will no doubt go far in conserving labor supply.

Fig 1—Reproduction of form used in job analysis for physical fitness requirements

A preliminary review of reports received from regional medical officers has revealed a wide variation in functional and environmental factors appertaining to positions of the same title in different localities and often in the same establishment. With the need for speeding up production, there has been a shift to the assembly line technique. This inevitably has brought a tendency toward specialization, this tendency is increased by the shortage of skilled labor and the lack of time for training inexperienced labor to handle more than one job. Whereas in the past a person with a rating in a particular trade was expected to do, and was capable of doing, all the duties of that trade, now the rating is given frequently to a man whose capabilities are limited to only a few of those duties. For example, a shipfitter's rating is given to a man who works aboard ship doing very arduous work requiring considerable agility and also to the man who works in the structural shop running a drill press or some similar machine. Volume of work may necessitate shifting these men to other shops. Obviously the minimum physical requirements of a man in the structural shop are considerably less than for the ship worker. Agility, acute hearing and vision in two eyes are essential for the latter, they are not essential for the former.

Many positions are not static—that is, a job may require light duties during one period of its operation and extremely heavy duties at another time. This was characteristic of the majority of the positions observed

in a large arsenal. At the Rock Island Arsenal the position title "classified laborer" is used in referring to an employee performing almost any type of work to which a definite classification has not been given. These employees are used as apprentices, helpers and the like and are elevated by successive grades to practically any classification. Therefore it is not possible to set down dogmatically the physical requirements for the position of classified laborer.

The survey of the position of blacksmith at the Washington Navy Yard reveals placement potentialities for persons who have lost one leg and who use a good artificial appliance. The survey of the same position at the New York Navy Yard shows that there are unavoidable hazards peculiar to that establishment which make placement of a person with such a defect inadvisable.

It is apparent, therefore, that general principles of placement relating to job families or constellations cannot be followed too closely in devising the manual, instead, it is being constructed so that a particular position in a particular establishment may be considered on an individual basis. It is expected that all considerations relating to placement will be tempered by the functional and environmental factors peculiar to each governmental establishment and also by results of consultation between the commission's medical officers and

Fig 2—Reproduction of reverse side of form shown in figure 1 giving recommendations of regional medical officer as result of survey

the medical adviser, safety engineer or other official responsible for the placement policy of the establishment.

Certain basic considerations are evident in devising the placement manual. One of them has to do with the prevalence of certain types of physical defects. Present problems in placement. All

on the frequency of physical disability must be treated as estimates. According to the National Health Survey³ made by the United States Public Health Service, prevalence rates are as follows:

Orthopedic Impairments—It is estimated that 2 out of every one hundred persons in the United States have a permanent orthopedic impairment of such serious nature that they are considered to be partly, or completely, crippled, deformed or paralyzed. On this basis there would be a total of approximately 2,500,000 persons in the United States with orthopedic handicaps, and 500,000 of them would have handicaps of such serious nature that they are incapacitated.

Chronic Disease—Estimates dealing with chronic disease other than tuberculosis and heart disease are not useful. It

nent or static. Acute, subacute or chronic disease processes of the bone, peripheral vessels and muscles causing orthopedic deformities are not considered in judicious initial placement, in view of the possibility of exacerbation involving one or more additional organs or members of the body. Such complications add to the physical limitations of the employee—limitations which cannot be anticipated in his vocational training. It is recognized also that the disease itself, apart from the resulting deformity, may add to the limitations on the employee's activity.

Of the orthopedic deformities met in civil service placement activity, experience has shown that atrophies

is estimated that 3,700,000 persons in the United States have a heart condition and that 680,000 have tuberculosis.

Blindness in One or Both Eyes—There are approximately 133,000 blind persons in the United States. Approximately 425,000 persons in the United States are blind in one eye. The latter group represents the important clue for placement potentiality in government industry at present.

Deafness and Hard of Hearing—This group has the largest potentialities in placement in government industry. There are approximately 65,000 persons in the general population who are totally deaf, 60,000 deaf mutes and an estimated 1,547,000 persons who are classed as being hard of hearing.

In dealing with these defects the commission is taking into consideration some fundamental principles in evaluating the results of the surveys made of positions.

In its placement activity the commission considers only orthopedic crippling conditions which are perma-

and deformities due to poliomyelitis and amputations (due to accidents) are the most common. These defects are considered as being static and persons with such defects are the most suitable in the orthopedic defects class for judicious placement in government industry. In the placement of the physically handicapped in the orthopedic group, the commission depends on complete preplacement medical reports of all persons being considered. When necessary, depending on the nature of the handicap, the commission's medical officers will request special reports from orthopedic specialists. The surveys indicate definitely that in no other type of defects is it more important to evaluate accurately the functional factors of the position than it is in determining individual limitations due to orthopedic defects. Although the surveys indicate that a large number of positions in governmental establishments have walking, standing or climbing as part of the duties, it is felt, on evaluating the survey reports, that placement oppor-

3 The Prevalence and Causes of Orthopedic Impairments. National Health Survey, Sickness and Medical Care Series, Bull. 4, 1935-1936.

tunities are afforded in a large number of these positions to persons with amputations of one lower extremity with a good orthopedic appliance

It is expected that in consultations between the regional medical officers and the medical and safety advisers, representing appointing officials, the question of floor hazards and dangerous machinery will be discussed. When these hazards exist, placement of a person with an unputated leg or foot is not advisable. Also certain establishments have an environment of intense heat and humidity which would not be suitable for persons with amputations of lower extremities who

ment picture for persons with arm and hand disabilities more favorable. It has been found that the range of suitability for such persons in governmental industrial employment can be determined only by a strict correlation of the extent of the impairment with a careful analysis of all functional factors of the arms or hands involved in the performance of duties of the position in question. If the functional factors indicate that only one good arm or one good hand is necessary, no particular attention is given to the efficiency of the orthopedic appliance of the defective member. The functional processes of numerous occupations in government

wear orthopedic appliances. One large establishment has a network of railroad tracks, and it is felt that in this establishment and in any other establishment in which there are extra occupational hazards due to locomotives, moving trucks and the like, persons with amputations who are wearing artificial parts should not be placed unless the management arranges for safe exits to city thoroughfares.

The survey reports are in unanimous agreement that machine-shop work is suitable for persons with one good leg and one artificial leg. Arm and hand disabilities have been found to offer more serious placement problems than defects of the lower extremities, except when the functional factors of the job are changed to meet the impairment. It is expected, however, that improvement in orthopedic appliances devised for arm and hand disabilities will go far in making the place-

industry can be broken up to allow for the loss of an arm or a hand. In other occupations, an artificial appliance and one good arm or hand would enable the handicapped person to perform the duties satisfactorily. In the majority of governmental industrial positions the loss of the ring or little finger on one hand has not been found to hamper the efficient performance of a job. Of course, loss of a thumb on either hand necessitates a careful review of the functional factors of the position, since this defect usually renders the employee incapable of picking up, holding and manipulating small articles—very common functional processes in a large number of skilled trade positions.

In assigning disability codes to positions involving heavy lifting, bending, long standing and other functions which place a strain on the body trunk or to positions involving a humid and damp environment,

the commission has ruled out defects such as ankylosis of the spine due to arthritis, for placement consideration.

The influence of occupation on the incidence and mortality of tuberculosis among wage earners has been the concern of industrial insurance companies and public health agencies for more than a generation. The commission is cognizant of the fact that in no other kind of physical defect does the environment assume such an important role in placement considerations. Factors such as extreme changes in temperature and humidity are considered unsuitable in the placement of persons with a history of tuberculosis. Since dusts containing a high percentage of silica have an adverse effect on

sive walking or standing, were not coded to indicate that placement potentialities for ex-tuberculous persons existed. Other factors that were considered in reviewing positions for placement potentialities were (1) the speed at which the employee must work, (2) the monotony of the work, (3) the vibration of the process involved, (4) the intensity, difficulty and strain involved and (5) the posture of the employee while performing the duties of the position. Factors 1, 2, 3, 4 and 5 may be considered the extrinsic or mechanical characteristics of the job. The commission was unable to consider, on the basis of information at hand, the intrinsic or psychological factors which have a bearing on

persons with a history of tuberculosis and are known to alter susceptibility to tuberculous infection, the commission, in designating placement codes for positions which have been reported to involve this hazard has not listed such positions as offering placement potentialities for persons with a history of tuberculosis. Those positions which were reported as involving exposure to fumes or gases also were not considered for ex-tuberculous persons. Positions reported as having adverse environmental factors for ex-tuberculous patients included certain metal trades and foundry positions, some toolmaker and toolgager positions and positions involving metal polishing and battery making.

Since it is well recognized that fatigue is unfavorable to the welfare of persons with a history of tuberculosis, those positions which were reported as involving strenuous physical activities, such as heavy carrying, lifting or pushing, constant stair or ladder climbing and exces-

sive walking or standing, were not coded to indicate that placement potentialities for ex-tuberculous persons existed.

Other factors that were considered in reviewing positions for placement potentialities were (1) the speed at which the employee must work, (2) the monotony of the work, (3) the vibration of the process involved, (4) the intensity, difficulty and strain involved and (5) the posture of the employee while performing the duties of the position.

Factors 1, 2, 3, 4 and 5 may be considered the extrinsic or mechanical characteristics of the job. The commission was unable to consider, on the basis of information at hand, the intrinsic or psychological factors which have a bearing on placement potentialities for ex-tuberculous persons.

Although this consideration, in connection with placement of ex-tuberculous persons, seemingly limits to a

large extent placement activity, a large number of skilled trades and light machine shop positions have been found on survey to be suitable for such persons and not to present the hazards discussed.

Hitherto very little has been done to effect placement of persons with heart disease in governmental industrial establishments. This defect is a common one and involves intelligent placement not only on the part of the employer but on the part of the medical advisers to management. Types of heart disease most frequently encountered on preemployment examinations for the federal civil service are rheumatic, hypertensive, syphilitic and coronary diseases.

The guiding principles in establishing disability placement codes relating to heart disease follow fairly closely the American Heart Association classifications. No attempt was made to interpolate in the disability placement code any consideration of the types of heart disease.

When surveys of positions indicated that the workers were performing duties in a damp environment or in an environment presenting sudden temperature changes, sentences will be added to the code to indicate that persons with a history of rheumatic disease should not be placed in these positions.

Persons with cardiovascular syphilis are considered the least satisfactory of all the cardiac patients from the standpoint of placement. The commission's statistics indicate that this defect has a high incidence in the laboring classes and in most instances incapacitates to the extent that vocational training and placement are difficult and, in view of the guarded prognosis of the disease, often inadvisable.

Persons with a history of coronary disease, manifested by angina pectoris, coronary thrombosis, cardiac asthma or paroxysmal dyspnea are not justifiable risks for initial placement in federal government industry.

Surveys have revealed a small number of positions in governmental industrial establishments in which persons with hypertensive heart disease may be placed, provided there is no history of decompensation.

Placement potentialities have been coded for a considerable number of machine-shop and drafting positions involving desk or bench duty. All positions in which the surveys disclosed that the performance of the duties involved climbing ladders, frequent climbing of stairs, stooping, pushing, crawling, frequent lifting or other types of arduous physical exertion have not been given disability classification codes to include cardiac disability.

Blind persons and persons with severe impairment of visual acuity receive very special consideration in placement. The commission's definition of a blind person is "A person with not more than 10 per cent visual acuity in the better eye when corrected by glasses or a visual acuity greater than 10 per cent but with a limitation in the field of vision such that the widest diameter of the visual field subtends on an angle no greater than 20 degrees."

The so-called industrially blind standard is considerably higher and may range from 20/70 to 20/100 (Snellen) with correction—that is, 63.8 per cent to 48.9 per cent visual efficiency with correction. Surveys have revealed numerous occupational and extraoccupational hazards in governmental industrial establishments which will limit placement of the blind, according

to the commission's definition, to a very small number of positions, in sheltered environments, involving repetitive work in which a sense of touch alone is required (certain inspector positions). The further utilization of blind persons in additional positions will depend on the willingness of the management to furnish safe transportation facilities for the blind within industrial establishments.

The industrially blind and those persons who are blind in one eye only, with good vision in the other, represent an important group with placement potentialities as far as government industry is concerned. The surveys reported in a large establishment indicated that approximately 90 per cent of the positions could be filled by persons who are blind in one eye and have good vision in the other. Since it is questionable whether or not one-eyed persons develop a true stereopsis or depth perception, it has not been considered wise to place these persons in dangerous positions such as those of crane operators working at a high elevation, operators of moving machinery, truck and tractor drivers and feeding machine operators and in structural and maintenance jobs in which the duties involve the use of scaffolding. In these positions surveys indicate that normal acuity, stereopsis, normal muscle balance and often normal color vision are essential. Poor distance vision, according to industrial standards, with good near vision is considered as being compatible with the efficient performance, with a minimum risk, of the duties of the following positions, in which extraoccupational hazards are not serious considerations: inspector, assorter, engineer and calibrating technician.

A large number of miscellaneous "in between jobs" in which unusual visual aptitudes are not required were discovered on survey. Such positions include laborer, certain types of mechanics, handyman, certain types of machinists and metalsmiths.

Those occupations which have been found on survey to be particularly hazardous, with the possibility of further damaging the visual apparatus, have not been coded to indicate that persons with one eye can be placed in these positions. Such positions include those in which corrosive solutions are used and those in which abrasive particles may be thrown into the eye by grinding or clamping tools.

The hard of hearing and the deaf group of the physically handicapped represent the largest group with placement potentialities. This fact has been recognized by the commission for some time, and under the provisions of an executive order of Dec. 1, 1908 deaf mutes and the hard of hearing are admitted to examinations for a large number of positions.

The recent surveys have disclosed that types of positions suitable for persons with hearing impairment are represented by a large number of jobs of the skilled, semiskilled or unskilled types that can be carried on without the need of extensive communication. The most suitable positions for the deaf have been found to be the positions of routine type in which the same operation is performed over and over again. The deaf are satisfactory employees in positions such as packer, checker, sorter, labeler, polisher, oiler and finisher and in a large number of similar positions.

The surveys reveal some positions in which it was apparent that deaf mutes might be better employees than

persons with normal hearing. Such positions include boiler maker and inspector of material equipment or inspectors of finished products where the need of communication is not important.

It is recognized that at present many hearing aids offer a benefit to the hard of hearing that is comparable to the benefit scientifically selected lenses offer to those with defective vision. Unfortunately there are still instruments on the market designed as hearing aids which lack efficiency, adaptability and durability. The efficient and serviceable hearing aid has broadened tremendously the placement potentialities of the hard of hearing group. Already a considerable number of the hard of hearing using efficient hearing aids have been employed in federal industry and in the federal civil

potentialities for machine shop jobs or structural shop jobs for the hard of hearing and the deaf, and it is not expected that many difficult placement problems will arise in utilizing the services of the hard of hearing and the deaf.

In both groups, of course, consideration must be given to psychologic or emotional maladjustment, which occasionally accompanies these defects and may make the handicapped person an unsuitable employee. It will be important for those persons responsible for placement in federal establishments to determine whether deaf or hard of hearing persons who are under consideration for employment have a healthy attitude toward their defect or environment before placement is attempted.

The employment of women in industry was given its largest impetus by the industrial revolution in Great Britain in the early nineteenth century. The appearance of many new mechanical operations in industry at that time was largely responsible for this trend. Since that time women gradually have assumed an increased importance in the labor market, especially during wartime when the male labor supply is scarce.

As far as physical ability is concerned, some women could be placed in any industrial position filled by male workers and most women, with proper training, could perform the duties of the majority of positions in industry with proper placement. Since a large number of women are limited in many respects as to physical ability to perform certain types of work in the industrial field and also have a high percentage of absenteeism due to illness for the purpose of any placement program they must be considered as presenting problems in placement or as "physically handicapped." For this reason the commission in making its surveys of industrial positions has attempted also to determine which positions in government industry could be performed by women.

One ordnance establishment was found to be employing 50 per cent women in one of its shops. These female employees were engaged in many different operations, including the grinding, polishing and plating of mirrors, prism assembling and inspecting. It was found that their work was excellent, and for some operations such as prism assembly, they were superior to men. Surveys reveal that in another ordnance establishment 85 per cent of the positions could be held by female employees, however, this establishment had very few female employees.

In coding positions which were found to be suitable for female employees and not already held by females, the commission followed the suitability classification as established by the U. S. Employment Service.

1 Positions in which women are now regularly employed.

2 Positions apparently suitable for women—those occupations in which women have been employed in some establishments in some parts of the country or occupations in which there is no apparent factor that would bar women.

3 Positions partially suitable for women—those occupations which have generally been considered to be suitable only for men but which on analysis were found to contain certain phases that did not entail excessive physical exertion and that could be taught within a reasonably short time. For example, it usually takes years of training to become efficient in all aspects of the position of precision lens grinder. Certain phases, however, such as blocking, cementing and inspecting, can be taught within a comparatively short time, and women have been found to be very adaptable to these tasks.

* A combination of disability code numbers listed for any particular position is not to be interpreted necessarily to indicate that a combination of all the defects would be acceptable for placement in that position.

1 With other member intact and fully functioning.

2 One or more fingers missing on secondary hand with good residual grasping power in that hand and normal function of primary hand. In some positions good grasping power not required in secondary hand.

3 Amputation of one lower extremity with satisfactory prosthesis and with other lower extremity intact and fully functioning.

4 One or more fingers disabled on secondary hand with good residual grasping power in that hand and normal function of primary hand. In some positions grasping power not required in secondary hand.

5 Sense of hearing nonfunctioning for ordinary purposes of life. Code number may include deaf mutes depending on amount of communication required in routine performance of duties of position in question.

6 Sense of hearing although defective functional with or without hearing aid.

7 Organic heart disease other than coronary disease fully compensated without history of decompensation.

8 Tuberculosis healed for a period of at least one year and health otherwise good. For some positions of sedentary type and with suitable working environment persons receiving collapse therapy may be considered.

service in general. Information derived from the complete survey will disclose an even larger group of positions in which persons who are hard of hearing but use efficient and serviceable hearing aids may be employed. Lip reading, motion pictures and familiarity of industrial vocabularies in training will broaden further the placement field in this class of defect.

In the placement of deaf and hard of hearing persons, extraoccupational hazards must be given due consideration. For example, a chipper in the navy yard may have hearing which is greatly diminished without affecting materially his efficiency or without his being a hazard to himself or others, however, owing to the fact that he is working in an open navy yard on ship construction around heavy moving machinery and locomotives, it is inadvisable to place him in an open navy yard, though he could work as an inside chipper. With very few exceptions, surveys have revealed placement

In utilizing the foregoing classification the commission gave consideration to the following factors in coding positions reported on the surveys

1 Factors Which Depend on the Female Constitution—Authorities disagree on the importance of the difference in the constitutional makeup between men and women and its relation to ability to perform heavy labor. However, it has been decided for the present that placement of women in government industry should be effected in positions involving duties of semiharduous or moderate nature. There is also disagreement on the influence of particular types of occupations on the menstrual cycle. In this connection most evidence points to the favorability of positions which alternate between standing and sitting for female employees, and such positions have been considered ideal for placement.

2 Factors Due to the Nature of the Work Itself—Women have been found to be particularly adaptable to industrial discipline and to have a remarkable capacity for performing repetitive and often monotonous work which calls for manual dexterity, precision and patience. A large number of women have already been employed successfully in federal arsenals, ordnance plants, quartermaster depots and navy yards doing work of this nature. Such positions include those of explosives operators, gas mask inspectors, aircraft material workers, leather and cabinet workers, parachute repairers and related positions.

Those positions disclosed on survey as involving heavy lifting or as being hazardous were not considered suitable for women in establishing the placement codes.

The foregoing discussion of the placement of the physically handicapped in government industry represents the picture as it is today. Depending on the duration of the war and resulting shortages in the labor supply, the picture will change. A greater number of additional positions may have to be found for the physically handicapped and a corresponding number of handicapped trained for these positions. Since the commission's placement manual will be in a loose-leaf form, allowing for changes in code designations either for the job classification or for disability, changing trends in the industrial field and in labor supply are provided for.

The commission's program will serve two purposes. It will promote the war effort by facilitating the training, recruitment and placement of qualified physically handicapped persons where they are needed, and it will offer the commission excellent experience which will be of great value after the war in utilizing the services of disabled veterans and those disabled as a result of accelerated industrial activity. It is expected that, depending on the duration of the war, large numbers of disabled veterans and industrial workers will be placed on the labor market.

Two Roads Are Always Open—A student of medicine begins his novitiate when he goes to medical school, but he should have entered upon his apprenticeship as a doctor many years before, when for the first time he was allowed free choice in his earlier education. At that point two roads are always open, one, straight and narrow, that leads through the sciences with only a few brief detours into general knowledge, the other, circuitous and serpentine, that wanders far afield dips more deeply into the wider realms of learning and returns to the highway only when necessity demands—this is the more entrancing road, for there are more flowers beside it, and from the ancient hills that it surmounts one sees the world more clearly. Although the doctor who has traveled this road must leave it for a space of years when his novitiate begins, when leisure later comes he can return to explore the inviting bypaths that branch on either side, but to him who has never trod it they are forever forbidden.—Irving, Frederick C. *Safe Deliverance*, Boston, Houghton Mifflin Company, 1942.

THERAPEUTICS OF PNEUMONIA ON A STATEWIDE BASIS

LIEUT. COMDR. EDWARD L. BORTZ
MEDICAL CORPS, UNITED STATES NAVAL RESERVE

The application of approved methods in the diagnosis and treatment of the different kinds of pneumonia has brought about a spectacular diminution in the mortality rate from this group of diseases during the last five years. Introduction of the sulfonamide compounds has made possible a therapeutic approach to the problem which if put to maximum use should directly remove pneumonia as one of the leading causes of death.

The persistence of a relatively high mortality rate throughout the nation, even though treatment under carefully controlled conditions has produced a conspicuous decrease in the death rate, remains one of the unsolved problems of the medical profession. For the nation at large the rate is somewhere between 12 per cent and 15 per cent. In well organized clinics and hospitals, where pneumonia is regarded as one of the great medical emergencies, modern methods of treatment have been so efficient that from time to time groups of 100 patients with pneumonia have been treated without the loss of a single life.

PIONEERS IN STATEWIDE CONTROL

To be more widely effective, the therapeutics of pneumonia, in the light of modern scientific knowledge, should be planned on a statewide basis. Only in this way will the lag between known medical science and its application be reduced to a minimum. Facilities for diagnosis, correct therapy and the collection of statistics need be set up for the assistance of the general practitioner.

Even prior to the changes in treatment occasioned by the advent of the sulfonamide compounds, Massachusetts and New York united the resources of their respective states and used the different kinds of serum that were reasonably satisfactory in treating pneumonia. The entry of the sulfonamide compounds at a time when serum therapy was becoming more and more effective, placed in the hands of the medical profession a double barreled weapon for the treatment of pneumonia that has stricken it from the upper position in the list of mortality statistics.

INCIDENCE

In 1936 more than 133,000 patients died from pneumonia and influenza in the United States. In the same year the mortality from pneumonia in Pennsylvania was more than 9,000 persons, ranking sixth on the list of causes of death.¹

Since it is generally conceded that without the benefit of serum or sulfonamide therapy a mortality rate of approximately 25 per cent may be assumed for all cases of pneumonia, it is reasonable to suppose that about 35,000 cases of pneumonia occur in Pennsylvania each

Read before the Section on Experimental Medicine and Therapeutics at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

¹ MacBride, Dexter, Edith, and Bortz, E. L. *Pneumonia Control Plan for Pennsylvania*. Pennsylvania M. J. 41: 279 (Jan.) 1938.

Every center is capable of sputum diagnosis, blood culture studies and the furnishing of simple laboratory procedures

Fifty-three of the pneumonia control centers are classified as major stations, having available serum for types I, II, V, VIII and XIV pneumococcus infections. The remaining stations are furnished with serum for types I and II. Sulfapyridine and sulfathiazole are available at all control stations.

2 *Treatment*—The procedure in Pennsylvania is to advocate the use of sulfathiazole or sulfadiazine for

During the period of 1940-1941, 68 patients were treated with serum alone with a total of 20 deaths, or a mortality rate of 29.4 per cent.

All types of therapeutic serum are held in readiness twenty-four hours a day at the office of the Division of Pneumonia Control in Harrisburg and for patients who cannot afford to pay the serum is granted without charge.

3 *Lay Education*—Under the leadership of organized medicine an elaborate educational campaign has been carried on for the past five years. The Division

All tables presented herein are taken from the annual report of the Pennsylvania Pneumonia Control Division of the Department of Health, Harrisburg, Pa., August 1941.

No. 133 signify the specific pneumococci types 133. 00 indicates that no attempt was made at typing. 40 more than one specific typed pneumococcus present. 88 sputum typed but no pneumococci were found. 99 typed and pneumococci were found but no specific type identified.

twenty-four hours as soon as the definite diagnosis of pneumonia has been made. If the patient is desperately ill and if the blood culture is found to be positive, serum in adequate quantity is immediately recommended. Since January 1942, sulfadiazine has been made available through the Division of Pneumonia Control, and, at the present time, it is the drug of choice in the treatment of pneumococcal pneumonia.

Although, at the outset of the campaign the importance of a bacteriologic diagnosis was stressed, it is now evident that during the last two years, since the sulfonamide compounds have become so prominent, physicians generally disregard bacteriologic studies. That this practice is to be decried must be emphasized, because in selected instances the use of serum has often proved life saving, particularly for patients who had reacted unfavorably to the sulfonamide compounds.

of Health Education under the expert supervision of Mrs. Edna M. Kech during the period from Jan. 1, 1941 to Dec. 31, 1941 arranged one hundred and twenty-nine pneumonia meetings with a total attendance of 46,250. During this period seven hundred physicians addressed various lay groups at the meetings which had been arranged for by Mrs. Kech. Commendation is due the practitioners for their support in this lay education program.

In addition to the meetings a motion picture on pneumonia has been prepared and in four months has been shown one hundred and ninety-nine times, to a total attendance of 22,822 persons.

4 *Education for the Physician*—For the medical profession seven semiannual conferences have been conducted. The attendance at each varied from seventy-five to one hundred and seventy-five physicians. Rec-

work on pneumonia was reviewed at these meetings and recommendations were made to the local county medical society. After reports from all of the societies a question and answer period was held, thereby giving all the opportunity to participate.

Diagnosis, as the key to the successful treatment of pneumonia, has been emphasized at all refresher courses that have been given in Pennsylvania. Physicians have been warned not to use serum in the absence of a specific bacteriologic diagnosis. Reports have indicated that the practice of prescribing one of the sulfonamide compounds for any infection of the respiratory tract

Now with the active participation of the Division of Pneumonia Control of the Department of Health, under the capable leadership of Dr. Dale C. Stahle, the reporting and tabulating of cases for statistics is carried on in a more efficient manner.

The most recent statistics from this department show that between the period of July 1, 1941 and Jan. 1, 1942, 1,445 cases of pneumonia have been reported with 162 deaths. Allowing for final corrections, the approximate mortality is 10 per cent. From July 1, 1940 to June 30, 1941, 1,500 private cases were reported to the Division of Pneumonia Control.

in the absence of a specific bacteriologic diagnosis was widespread.

To keep the vital facts before the general practitioners, bulletins are flashed throughout the commonwealth at intermittent periods. The latest series of these has been compiled into a brochure entitled "New Facts on Pneumonia" and is distributed to every county medical society, through which the facts are made available to every practicing physician in the state.

5 Case Reporting.—No statistics are available regarding the extent of the pneumonia problem previous to 1937, at which time it was made a reportable disease. The Commission of Pneumonia Control, before the creation of the Division of Pneumonia Control in the Department of Health, attempted to collect statistics through the members of the commission and local representatives. A series of 5,977 cases in the 1938-1939 season was compiled by the Sub-Committee on Statistics of the State Commission.

STATISTICS

From a recent Metropolitan Life Insurance Company survey this disease caused only 41.9 deaths per hundred thousand policyholders during the first three months of the current year. This is 18 per cent below the rate in the same period of 1941, 37 per cent below the average for the last four years and 61 per cent below the average for the five years previous to the advent of the sulfonamide compounds.

A careful study of the mortality data available since the turn of the century indicates that there was a slight general trend downward of the death rate even before the efficacy of the present agents was developed. Since 1937, however, there has been a sharp and continuous declination of the mortality curve effective for men, women and children of all age groups.

As a disease pneumonia is very much on the spot at the present time. For every patient who dies some one is usually to blame—either the patient, owing to

lack of prompt resort to modern medical care, or the attending physician from lack of knowledge of what modern science has to offer. In the absence of pronounced complications and given a reasonably good constitution, the patient suffering from pneumonia today should not die.

In a closely reasoned and well documented paper presented a year ago, Stahle demonstrated a mortality rate of 9.19 per cent in a series of 15,251 patients

general practitioners, who, in the last analysis, are the key men in the control of pneumonia.

Each year, approximately three thousand physicians, or 97 per cent of the total number utilizing the facilities of the distributing centers, send in report cards on their cases. These cards, which are furnished by the Division of Pneumonia Control, permit accurate classification of the cases with reference to age, sex, color, duration of the disease, frequently whether or not there

*Percentage of all treated cases developing these complications

treated by the physicians of Pennsylvania.⁴ Experience with the sulfonamide compounds has been so satisfactory that the attending physicians have reduced the use of serum to a minimum (table 1).

The supervision and collection of data dealing with the pneumonia problem in highly industrial communities such as Pennsylvania, is a huge task. Organized medicine and the department of health have waged a campaign which has had the unqualified support of

is a positive blood culture, and, when given, the type of organism together with the kind of therapeutic agent and quantity administered. Red tape has been reduced to a minimum. When the cards are received in the Bureau of Pneumonia Control they are directed to the Bureau of Vital Statistics. Every case reported is classified and coded on an international code, which eliminates all questionable features of the cases and places them in the proper category.

In 1936 at a time when there was no way of collecting statistics for this purpose, the approximate number

⁴ Stahle, D. C. A Clinical Analysis of Fifteen Thousand Cases of Pneumonia. J. A. M. A. 118:440 (Feb. 7) 1942.

of pneumonia deaths in Pennsylvania was 9,000. The most recent study by the Division of Pneumonia Control shows an incidence of 9,295 from July 1, 1940 to June 30, 1941, with a total mortality rate of 11.69 per cent. While this indicates a substantial drop over the former rate, it nevertheless is still too high.

Of 1,956 patients treated at home there were 109 deaths, or a rate of 5.57 per cent. Of 7,326 patients treated in the hospital there were 977 deaths, or a rate of 13.34 per cent. This can readily be explained by the fact that the patients with the more serious pneumonia had been sent to the hospital (tables 2 and 3).

In a critical appraisal of statistics, caution must be paid to the presence of complicating factors in order to dismiss the possibility of deaths caused by complications per se being counted primarily as pneumonia deaths. Example: Of 242 patients with pneumonia, 31 had meningitis, 5 had a pulmonary embolism, 5 had pericarditis, 15 had cancer and 39 had heart disease, while

the death rate from pneumonia without the aid and cooperation of the department of health.

Pneumonia is a specific disease. It has a definite onset and method of spread. Effective therapeutic agents are now available. The problem, then, is to have a highly trained corps of workers in the field, physicians and nurses who will regard pneumonia as the great medical emergency, strive to make an accurate and prompt diagnosis and institute treatment immediately following diagnosis.

Instructing the public to avoid contact with respiratory infections and maintain sound health habits with regard to diet, elimination and rest and visit promptly the family physician when troublesome symptoms occur serves a twofold purpose. First, it maintains the public resistance at an optimum level, second, it places the patient in the hands of the physician at the earliest time in the event that involvement of a lung occurs.

Prompt action on the part of an enlightened laity and a well trained, alert medical profession would reduce the mortality rate from pneumonia to a spectacular low.

10 had peritonitis and 25 had cerebral thrombosis (table 6). Of this series of 242 patients 54 died within twenty-four hours.

Resort to the use of effective chemotherapeutic agents early in the treatment of respiratory infection has cut down the number of pneumonia deaths. Likewise fewer patients are being sent to the hospital. It may be that during the next few years a plateau in the mortality rate will have been reached until the frontiers of pneumonia control are extended to include immunization and prophylaxis.

CONCLUSION

According to Haven Emerson the preservation of community health is the major responsibility of the public health officials, whereas the problem of the individual and his health needs is the domain of the general practitioner.

Pneumonia control is the joint responsibility of the public health representative and the private physician. The public health official without the utmost cooperation on the part of the medical profession cannot hope for any substantial success in wiping out the ravages of pneumonia, nor can the private physician nor the county or state society carry on a campaign to reduce

SUMMARY

Mortality from pneumonia is steadily decreasing. To propagate this trend further modern methods of attack have been evolved. Organization on a statewide basis in Pennsylvania has played no small part in this decline. In 1936 there were approximately 9,000 pneumonia deaths during the 1937-1938 period 7,117 persons died from this disease, from July 1, 1940 to June 30, 1941 9,295 cases were reported, with a mortality of 10.87, and the latest statistics show that from July 1, 1941 to Jan. 1, 1942 the total number of pneumonia cases reported was 1,445 with one hundred and sixty-two deaths.

One hundred and seventy-eight pneumonia control centers located at strategic points throughout the commonwealth are prepared to furnish the physicians with necessary laboratory procedures, serum and sulfonamide compounds for treatment.

Meetings for the public are being routinely conducted for education in the rudiments of precaution and prompt action when a respiratory infection appears.

An extensive series of meetings for physicians has been conducted annually since 1937.

Statistics are collected by the report card system.

Physicians are becoming more and more alert to the gravity of this emergency and the significance of prompt diagnosis and quick action.

ABSTRACT OF DISCUSSION

Dr. H. A. REIMANN, Philadelphia: The mortality rate from pneumonia of all kinds has declined steadily during the past forty years and so has the mortality rate from many other infectious diseases as well without the aid of specific measures. The improvement was apparently brought about by many complex factors including increased knowledge, better housing and better food. Specific serum treatment no doubt was effective in reducing the death rate in pneumococcal pneumonia more rapidly in the past ten years but sulfonamide chemotherapy, as every one knows, has caused the greatest good. Dr. Bortz is concerned with the present mortality rate of between 10 and 15 per cent in properly treated cases of pneumococcal pneumonia. It is probable however that we can never improve much on this figure, which may be near an irreducible minimum, even if better drugs are eventually synthesized. There is a certain percentage of cases with serious focal complications such as endocarditis or pericarditis with overwhelming infection, or the

causative pneumococci may become drug fast, or treatment might be delayed too long, or there may be coincident chronic disease such as diabetes, heart failure or renal failure, in which specific therapy at present seems futile. Nevertheless he is correct in urging that every effort be made to control even such cases. It has been found by long experience that the successful epidemiologic control of infectious disease is seldom accomplished by the efforts of the individual practitioner alone. For many reasons it is a matter for public health officials to contend with, as Dr Bortz has shown. The initiation of such efforts should properly be made by qualified state or other health officials but unfortunately such positions in many localities are not staffed with properly trained or interested personnel. It is highly commendable, but it should not have been necessary, for a group of busy practitioners to give their time to institute and organize a campaign such as the successful one described by Dr Bortz, however, it shows what doctors can do when the need arises and they have the will to do it. A word should be added in respect to the advice broadcast in many of the antipneumonia campaigns to give one of the sulfonamide drugs as soon as the diagnosis of pneumonia is made. It must be remembered that there are many kinds of pneumonia and for certain forms among them sulfonamide therapy is of no value. It is necessary therefore to make etiologic diagnosis in all cases as early as it is possible to do so. It is perhaps justifiable in most cases of pneumonia to administer the drugs promptly but if it is found that the disease is not caused by an infectious agent which is amenable to chemotherapy the drug should be stopped.

DR WALTER F. DONALDSON, Pittsburgh. I discuss this topic from the point of view of the various county and state medical societies. In Pennsylvania we have been particularly fortunate in the leadership typified in Dr Bortz. Our state medical society takes a part in this program, which costs more in sustained effort than in money. We carried the educational program to our entire membership in every county of the state. Dr Bortz organized his commission on our councilor district basis twelve councilor districts with one to seven counties to a district. The commission includes practitioners and teachers who know pneumonia, at least one from each district. On them falls considerable responsibility for inspiring interest by the membership throughout the various county medical societies in their respective districts. The state medical society has played a part by paying expenses of these commission members and of county society representatives to the meetings which Chairman Bortz plans and conducts twice a year at Harrisburg. It also cooperated by distributing literature to the membership throughout the various county medical societies, not reprints but preprints. Thinking of pneumonia as a seasonal disease, Dr Bortz gathers his copy early and we distribute preprints to county medical societies in December so that our members may have late information conveniently at hand. The preprint is not made up of long or dreary discussions of pneumonia by physicians in laboratories or alone by full time men in hospitals. The members of this commission meet the same problems in the early recognition and adequate treatment of pneumonia as does the general practitioner. In the 1942 preprint "New Facts on Pneumonia," no article contains more than a thousand words. They cover a dozen phases of pneumonia each written by a practitioner of current experience. We not only distribute these preprints at component society meetings in December but in January and February they appear in the *Pennsylvania Medical Journal*. Further, through the state medical society the twelve articles comprising "New Facts on Pneumonia" are multi-graphed, two or three at a time, and distributed to the publications of twenty-nine county medical societies, which print the entire series. Through such cooperation and the repetition through varied channels, our membership cannot readily avoid acquaintanceship with progress in the control of pneumonia. Programs at county medical society meetings include this subject. Essential cooperation in this yearly program between our state health department and the Medical Society of the State of Pennsylvania has been magnificent.

THE NATURAL HISTORY OF RHEUMATIC CARDIAC DISEASE A STATISTICAL STUDY

II. MANIFESTATIONS OF RHEUMATIC ACTIVITY RECURRENCE, SEVERITY OF INFECTION AND PROGNOSIS

ALFRED E. COHN, M.D.

AND

CLAIRE LINGG

NEW YORK

That rheumatic fever or rheumatic cardiac disease is a chronic infectious disease is now generally accepted. In children especially recurrent manifestations of an active inflammatory process are commonly observed. One or more such recurrences took place in 75 per cent of the 3,129 patients studied in this investigation during an average period of thirteen years after the onset of the illness.¹ Two recurrences were experienced by 51 per cent, three by 32 per cent, four by 20 per cent and five or more by 12 per cent.

Although recurrences² of rheumatic activity take place at all ages at which the disease is found it appears that the largest number occurs between the ages of 5 and 14 years. A curve representing the ages

Chart 1—Recurrences of rheumatic activity taking place usually before the age of 16

at which reactivations occur shows a sharp decline beginning at the age of 11 or 12. After the age of 20 it resembles a horizontal line. Before 13, recurrences are more frequent among girls than among boys (chart 1).

RECURRENCES RELATED TO AGE

It has been reported that recurrences of rheumatic activity are more commonly experienced the earlier the age at which the disease is acquired.³ A number of studies have shown that the tendency to infection begins to diminish about the age of puberty, suggest-

This study was made in collaboration with WPA Official Project No 65 197 WP 33 (N. Y. C.)

From the Hospital of the Rockefeller Institute for Medical Research and the Heart Committee of the New York Tuberculosis and Health Association Inc.

1 Cohn A. E. and Lingg Claire. The Natural History of Rheumatic Cardiac Disease. I. Onset and Duration of Disease. *J. A. M. A.* 121:1 (Jan 2) 1943.

2 Among recurrences of rheumatic infection are included active carditis (presence of an active rheumatic process in the heart clearly recognizable clinically), polyarthritis, Sydenham's chorea, subcutaneous nodules and manifestations of subacute activity. The term subacute activity is used to designate signs and symptoms of infection such as fever, tachycardia, joint pains, elevated erythrocyte sedimentation rate, leukocytosis or epistaxis otherwise unexplained and of insufficient degree to warrant a diagnosis of polyarthritis or carditis. Muscle or joint pains alone were not included as rheumatic reactivations because it was not possible to separate nonrheumatic pains from joint pains typical of subacute rheumatic fever. The incidence of such complaints without this discrimination has nevertheless been analyzed (chart 6 and tables 1 and 2). They were likewise considered in classifying the degree of infection to be referred to later.

3 Wilson M. G., Lingg Claire and Crawford G. Statistical Studies Bearing on Problems in Classification of Rheumatic Heart Disease in Children. *Am. Heart J.* 4:164 1928.

ing that a condition of resistance then develops.⁴ Some observers have presented data in support of the belief that, regardless of age, recurrences are less likely to occur five years or more after the first infection⁵ because of the development of immune processes. But

Chart 2—Recurrences of rheumatic activity in different onset groups

in most instances the onset is at 7 or 8 years. Five years after onset frequently coincides, therefore, with the beginning of puberty. It has been suggested that the decrease in recurrences noted at puberty may be due not to this physiologic change. The confusion, to repeat, occurs because five years after the onset of most cases, at 7 or 8 years, the age of puberty has arrived.

Further light is thrown on this point by curves showing the annual rate of recurrence in groups of patients in whom the disease began at different ages (chart 2). The shaded areas represent the years of puberty (ages 11 to 15), which, according to Stratz,⁶ comprise the second phase of the preadolescent period—proceritas II.

It appears that when the onset is under age 5 the rate of recurrence does not decrease at the end of five years but remains high for eight or nine years, or

until the beginning of puberty (chart 2A), but when the onset is between 5 and 7 the curves begin to decline earlier, after four or five years (ages 11 or 12), at the beginning of puberty, and when the onset is between 8 and 10 the fall begins two or three years later, although this too is at age 11 or 12 (chart 2C). When the onset is at the beginning of puberty, between 11 and 13 however, the rate of recurrence is lower in the first five years than when the onset is earlier, and the curves show a gradual decline almost from the beginning (chart 2D), when the disease begins after puberty, at ages 14 to 16 the rate of recurrence is considerably lower at the start and the curves resemble horizontal lines (chart 2E). These curves tend to support the opinion that it is puberty and not necessarily the first five years after the initial infection, that influences the frequency of recurrent activity.

There can be little doubt that knowledge of this diminishing susceptibility to rheumatic infection at puberty is of value in judging the effect of therapeutic measures on the subsequent course of the disease and that age therefore is an important factor in estimating the effect of treatment.

TYPES OF INFECTION

Of the various types of infection experienced throughout life pure forms—carditis, subacute, activity, polyarthritides, muscle and joint pains or chorea—occur in

Chart 3—Survival and severity of rheumatic infection in onset period

a little less than one fourth of all the cases when the onset takes place in childhood (chart 6, table 1). Polyarthritides is the most common single manifestation, experienced recurrently in 15 per cent of the cases. Carditis is the most frequent but is rarely the only

type of infection. It was exhibited at some time by nearly three fourths of the cases.

As the age at onset advances pure forms become more common. Among patients first affected in adolescence for example polyarthritis alone occurs in 40 per cent. When the disease begins in the third

decade this increases to 43 per cent but shrinks to 22 per cent when the onset is after 30. The later the disease begins the fewer are the patients who exhibit carditis and the greater becomes the number without manifest infection—more than half, for example, when the onset is after 30.

This description of male cases suffices also for females.

AGE AND SUSCEPTIBILITY TO TYPES OF INFECTION

Investigation of susceptibility at different ages to different types of infection discloses the fact that at all ages polyarthritis is the most common manifestation, and active carditis comes next, that during adolescence carditis is almost as frequent as polyarthritis, that polyarthritis is at all ages the most outstanding single manifestation (table 2). During adolescence nearly a third and after the age of 20 at least 50 per cent exhibit no signs of infection.

CLASSIFICATION OF SEVERITY

The severity of the rheumatic infection may have a bearing on prognosis. Coombs⁷ pointed out that prognosis is worse when patients show signs of systemic saturation with rheumatic infection. It has not been possible in this study to classify accounts of individual attacks according to severity, for this the records were too subjective to be reliable. The attempt has been made, however, to classify patients according to the degree or dose of rheumatic infection experienced in successive periods of life—childhood, adolescence, early, middle and late maturity.

To this end there were appraised (1) the manifestations presented—active carditis, polyarthritis, chorea, nodules, subacute activity, or muscle and joint pains⁸—and (2) their persistence—whether during a given period they were more or less continuous, whether

they recurred from time to time and the frequency of their recurrence, whether there were relatively long periods during which they were absent.

As a result, the following classification is proposed:

- 4+ when manifestations, carditis being one, are more or less continuous or recur at least four times
- 3+ when manifestations, carditis being one, recur less than four times or when with one attack of carditis, (a) muscle or joint pains persist throughout the period or (b) every type of manifestation is absent for not more than four years
- 2+ when manifestations including polyarthritis, chorea and subacute activity persist or recur at least five times, or when, after one attack of carditis, every type of manifestation is absent for a period of five or more years
- + when manifestations including polyarthritis, chorea or subacute activity recur not more than four times, even though muscle and joint pains may be continuously present
- ± when there are no manifestations or only persistent or recurrent muscle or joint pains

SEVERITY OF INFECTION RELATED TO AGE AT ONSET

Of those patients for whom the data were complete (2942, or about 95 per cent), infection was classified as severe (4+, 3+) or as moderately severe (2+) in 45 per cent,⁹ as mild (+) in 34 per cent and as questionable or absent (±) in 21 per cent (chart 4). The proportion of severe cases decreases as the age at onset increases. The proportions with severe or moderately severe as against mild or questionable activity were, for example, 58 per cent and 42 per cent respectively when the disease began in childhood, 30 per cent and 70 per cent when it began during adolescence, 12 per cent and 88 per cent when it began in early maturity, 10 per cent and 90 per cent when it began in middle maturity, and 3 and 97 per cent when it began after age 45.

In short, when the disease is acquired in childhood, of every 10 patients, 6 will exhibit severe infection and 3 mild and 1 will not experience more than muscle or joint pains in childhood. When the onset is in adolescence, out of every 10 cases infection will be severe in 3, mild in 5 and absent in 2. Of every 10 patients who acquire the disease in the twenties or between ages 30 and 45, only 1 in each group will suffer severe infection, 5 and 3, respectively will suffer mildly and 4 and 6 will not exhibit any signs of activity. When afflicted after the age of 45, 9 out of 10 will show no signs of activity.

Chart 5—Severity of rheumatic activity in different age periods

AGE SUSCEPTIBILITY TO SEVERITY OF INFECTION

It is in the early years of life that the infectious process is most active (chart 5). Severe infection is most common in childhood, occurring in 50 per cent. With advancing age the number of severe cases become

⁷ Coombs C. F. The Course of Rheumatic Heart Disease. M. J. & Rec. 121: 623 (May 20) 1925.

⁸ Muscle and joint pains were not included as manifestations of rheumatic fever when they occurred after the age of 15.

⁹ Broken down the classifications are 4+ in 21 per cent, 3+ in 17 per cent and 2+ in 7 per cent.

less frequent. During adolescence and in early maturity it is greatest among persons who have survived the disease since childhood. After the age of 30 the number of severe cases is relatively small, regardless of when the disease was acquired.

Severity of Infection and Prognosis—When the infection was classified as severe in childhood, only 34 per cent (4+) and 56 per cent (3+) of patients

lived through early maturity (the twenties) and only 11 per cent through middle maturity (30 to 45). This poor expectancy does not depend, it seems, on more severe infection later, for only 15 per cent of the patients who survived adolescence (chart 5) presented severe infection during the third decade, and of those who survived beyond this decade not more than about one tenth presented severe infection later.

survived childhood, whereas when the classification was moderately severe (2+) or mild (+), more than 70 per cent of them did survive (chart 3). Of the former patients (4+ and 3+) only 7 per cent and 12 per cent survived adolescence and only very few, 1 per cent and 2 per cent, survived the third decade. Of the latter patients (2+ or +), on the other hand, between 34 per cent and 59 per cent survived adolescence.

It is of particular interest that when the infection was mild (+) in childhood only about a third sur-

The curves of survival were furthermore consistently lower when activity was classified as ± early in the disease than when it was classified as +. Here again subsequent activity does not explain this less favorable prognosis, since few patients with onsets classified as ± exhibited manifestations later in life (charts 4 and 5). The explanation may be that among these patients continuous or recurrent carditis may, nevertheless, have been present though not recognized clinically or that with time myocardial insufficiency may have developed with or without obvious infection.

TYPE OF ONSET RELATED TO SUBSEQUENT INFECTION

Coombs⁷ believed that the kind of onset influenced the duration of life. When chorea came first, only 1 patient in 30 died of heart disease in the first decade, but with carditis more than 1 in 4, with polyarthritis 1 in 5 and with subcutaneous nodules 1 in 2.

To make predictions beyond one decade on the basis of onset alone is, however, impossible, since reactivations after the age of 10 are common and since the frequency as well as the type of recurrence plays an important part. Obviously, with chorea at the age of 6 or 7 years, prognosis may not be better than with carditis if the choreic child presents active carditis later on. It seemed better, therefore, to relate the type of onset to the degree of infection experienced in subsequent years. After the first two decades as has already been shown¹ carditis and chorea are rare but when carditis came first in children activity was severe during child-

hood. At all ages, polyarthritis is the most frequent single manifestation. It is the only manifestation exhibited by 40 per cent of patients between the ages of 15 and 30. After 30 years of age there is no manifest infection in about half of all patients.

The earlier the age at onset, the greater is the chance that infection will be "severe" during the next few years.

When the infection is "severe" in the early years of the disease expectancy is shorter than when the infection is "mild." Of children with "severe" infection, less than one-half survive childhood, about one-tenth survive adolescence and less than 2 per cent survive the third decade. Even when the infection is "mild" in childhood, only a third survive to the age of 30, and only one tenth to the age of 45.

Prognosis is less favorable with "mild" signs of infection in childhood than in older persons with the same degree of infection.

Chart 6—Types of infection experienced throughout life. Onset in childhood. Carditis the most frequent but rarely the only type of infection. Onset in adolescence and early maturity. Polyarthritis the most common manifestation. Onset after 30. No manifest infection at any time in most cases.

hood in 78 per cent and mild in 22 per cent (table 3). With other onsets, the degree of activity fell, it was severe in about 40 per cent and mild in about 60 per cent.

In adolescence, when the first manifestation was carditis, activity during adolescence was severe in only 55 per cent and mild in 45 per cent. With other onsets it was mild or absent in at least 80 per cent. After the age of 20, activity remained mild or absent in more than 90 per cent, whatever the onset.

SUMMARY

Recurrent manifestations of activity have been analyzed in 3,129 cases of rheumatic cardiac disease.

Recurrent manifestations are most common during childhood.

They are most prevalent before puberty rather than during the first five years after onset.

When the disease begins in childhood, carditis is the most frequent but rarely the only type of infection.

When the first manifestation of rheumatic fever is carditis, the chances are 3 to 1 that infection during childhood will be "severe." When the onset is characterized by joint symptoms or chorea or by a cardiac murmur alone, the chances are 3 to 2 that infection will be "mild." In adult life infection is "mild" or absent in 9 out of 10 cases, whatever the onset.

RENAL BLOOD FLOW AND GLOMERULAR FILTRATION

AS INFLUENCED BY ENVIRONMENTAL
TEMPERATURE CHANGES

GEORGE V BYFIELD, MD

STANLEY E TELSER, MD

AND

ROBERT W KEETON, MD

CHICAGO

Observations on the renal circulation were carried out as early as 1883, when Cohnheim and Roy¹ applied the oncometer to this problem. Since then Landergrén and Tigerstedt,¹ using the Ludwig stromuhr, and others² using modifications of the stromuhr method have extended the observations on direct measurements of renal blood flow. Van Slyke and his co-workers³ contributed an indirect method based on the renal urea extraction ratio and arrived at the conclusion that the urea clearance varied directly as the blood flow. These methods are not applicable to a study of renal blood flow in man. Smith and his associates⁴ developed the diodrast method, an indirect one, applicable to human subjects. Using this method White⁵ and others⁶ have contributed additional studies.

Barbour⁷ and Lazinski⁸ studied circulatory adjustments to hot environmental temperatures, but their work did not include the effect of such temperatures on the renal circulation. In an attempt to evaluate the effects of heat on the kidney, Goldring⁹ and Farr and Abernethy¹⁰ applied the urea clearance to febrile patients suffering from infectious processes and reported increases in clearances during the febrile stages.

10 Farr L E and Abernethy T J Renal Physiology in Lobar Pneumonia J Clin Investigation 16: 421 1937

Patients over 40 years of age with pneumonia did not show increases in clearances¹⁰ Farr and Moen¹¹ induced hyperpyrexia in rheumatic patients and found clearances 75 per cent of normal when fever was at its maximum Grant and Medes¹² found no correlation between body temperatures and creatinine clearances in human subjects with fever due to infection. They did, however, find a general parallelism between body temperature and creatine clearances in dogs made hyperthermic by diathermy. Page¹³ concluded that there was no significant alteration in renal function in patients with Bright's disease treated with diathermy.

Based on the principles developed by Lefevre¹⁴ and Burton¹⁵ a new method was developed for the measurement of peripheral blood flow. Extensive studies of changes induced in this flow by environmental temperatures have been made by Hardy and Du Bois¹⁶ and Winslow, Herrington and Gagge¹⁷. One of us (R W K), working with Hick, Montgomery, Glickman and Wall,¹⁸ has shown further that in hot environmental temperatures the body adjusts itself in the following manner:

1 There is no increase in cardiac output until heat is stored and the body temperature is elevated

2 The blood volume is usually not increased but in some subjects an increase of 10 to 15 per cent was noted. When dehydration occurs there may be a reduction in volume

3 The vital capacity is increased

4 There is a fourfold increase in peripheral blood flow

Since the increase in blood volume was not proportional to the increase in peripheral blood flow, it is obvious that the extra blood was shunted from the interior.

It therefore seemed important to study the effects of this shunt on the renal circulation.

EXPERIMENTAL PROCEDURE

An air conditioned room without windows was available for these studies. The temperature and humidity could be closely regulated. Air currents were minimal (15 to 25 feet per minute) and under equilibrium the air and wall temperatures were the same.

A 10 per cent "solution of purified mulin"¹⁹ prepared in 50 cc ampules for intravenous injection was used in our earlier experiments. In later ones we used mulin (Pfanzstich C P and Eastman C P) which was prepared in a 10 per cent solution in isotonic solution of sodium chloride and passed through Seitz

filters²⁰ "EK" Seitz filter pads gave us uniformly pyrogen free solutions. The diodrast²¹ used was a 35 per cent sterile solution obtained in 20 cc ampules.

ANALYTIC TECHNIC

Quantitative analysis of inulin in the blood serum and urine was carried out by our modification of the method described by Alving, Rubin and Miller²² and Alving and Miller²³. This modification allowed phototometric readings (Cenco-Sheard-Sanford photometer, Cenco filter No. 4) on filtrates containing 2.5 to 100 mg of inulin per hundred cubic centimeters of serum (or urine). This was made possible by using less filtrate, so that our final mixture in the tube for development of color contained 13 per cent less water and a higher percentage of hydrochloric acid and diphenylamine.

Diodrast analyses were determined after the method of White and Rolf,²⁴ using cadmium sulfate instead of trichloroacetic acid in preparing the protein free filtrate.

Inulin and diodrast clearances were then determined, the periods varying from ten to twenty minutes each. The inulin blood serum level was usually over 10 mg per hundred cubic centimeters. The level of diodrast was kept under 5 mg per hundred cubic centimeters for renal plasma flow and over 10 mg per hundred cubic centimeters for diodrast studies of the maximal rate of tubular excretion. All the patients were catheterized and the bladder emptied by successive washings with isotonic solution of sodium chloride. The residual bladder fluids were removed by insufflation through the catheter.

In our earlier tests we administered diodrast subcutaneously, a 35 per cent solution being diluted 1:3 with isotonic solution of sodium chloride after the method of White and Findley.²⁵ This gave a satisfactory level for determination of renal plasma flow. Inulin was given intravenously in a single injection of 50 cc of a 10 per cent solution after the method of Alving and Miller.²³

† Forty-five minutes after dye was given to this particular patient.

‡ Maximal clearance. S, standard clearance.

§ Given pentothal sodium intravenously instead of sodium amytal. Cardiac size was considered normal in all cases as estimated by

examination of the 2 meter roentgenograms of the chest.

PROCEDURE

The subject was placed in the air conditioned room before midnight of the day preceding the test and given water ad libitum until midnight. He was required to sleep in the nude at a temperature of 83.5 F (dry bulb) and 59 F (wet bulb), giving a relative humidity of 21 per cent, which is within the comfort zone of Houghten and Yaglou.²⁶ At 6 a. m. the patient was given 600 cc of water at body temperature. Studies of oxygen consumption and skin and rectal temperatures were begun at 7 a. m. Immediately thereafter the blood required by our studies was drawn.

Subsequently a continuous intravenous drip of a suitable mixture of inulin, diodrast and isotonic solution of sodium chloride as described in the method of Goldring, Chasis, Ranges and Smith²⁷ was used. The amount of diodrast varied with the type of study.

At the termination of the clearances under comfortable conditions, the temperature of the room was changed to hot dry (dry bulb 99.5 F, wet bulb 68.5 F, relative humidity 19 per cent) or hot wet (dry bulb 99.5 F, wet bulb 84.4 F, relative humidity 55 per cent). Under the hot condition all the heat must be lost from the surface by evaporation, since the temperature of the surrounding air is equal to or above that of the body temperature. All the heat arising within the interior of the body must be transported by the blood as it flows through the peripheral surfaces. This means that

the peripheral blood flow must be maximal to prevent a storage of heat and a rise in rectal temperature.

After a period adequate for the temperature change to occur and for equilibrium to be reached, clearances were repeated.

TYPES OF CASES STUDIED

Cases studied included normal persons, patients with early and established essential hypertension and patients with chronic glomerulonephritis both with and without

TABLE 2—Environmental Temperature Conditions

	Dry Bulb F	Wet Bulb F	Relative Humidity
Comfortable	67.5	59.0	21%
Hot dry	80.5	68.5	19%
Hot wet	80.5	81.4	65%

Air currents—15-20 feet per minute
Under equilibrium—Air and wall temperature the same

nitrogen retention. There was 1 patient with uraemia and normal tension and 1 patient with a well established hypertension who had suffered trauma to the right kidney.

The diagnosis of essential hypertension was made on patients with a high systolic and diastolic blood pressure who had had no known inflammatory kidney disease or urinary tract obstruction. Chronic glomerulonephritis was diagnosed on the basis of history of renal inflammatory disease and a study of urine sediment.

Among other clinical and laboratory studies carried out on our patients (table 1) were kidney function tests including urea clearances, phenolsulfonphthalein excretion tests (intravenous method) and urine concentration tests according to the method of Lashmet and Newburgh,²⁸ hourly blood pressure records for an entire day, blood pressure responses to sodium nitrite and sodium amytal, the cold pressor tests of Hines and Brown,²⁹ intravenous urograms, permanent records of the ocular fundi,³⁰ electrocardiograms and a 2 meter roentgenogram of the chest for heart size. Changes in the ocular fundi were graded according to the classification of Keith and Wagener.³¹

RESULTS

Extent of Peripheral Blood Flow—Studies were made of the peripheral blood flow of a normal subject and of subjects with essential hypertension and chronic

glomerulonephritis, using the method described by Keeton, Hick, Glickman and Montgomery.³² The environmental conditions used in our studies are summarized in table 2.

It will be noted in table 3 that the blood flow was increased in each instance approximately four times. This indicates that patients with normal and damaged kidneys have similar quantitative reactions and that kidney damage has not affected the transfer of blood from the interior to the surface.

Inulin Clearances—Inulin clearances under comfortable conditions in 3 normal subjects (R E, L W in table 4 and L C in table 6) averaged 110 cc to 173 square meters of body surface. This value is lower than the mean clearance of 131 cc as reported by study of a large series of cases by Smith.⁴ However, this falls within the variations of his mean and is also near the figure of 116.89 cc by Foa and his co-workers.³³ Twenty patients of all types were found to have the same inulin clearances in comfortable and in hot conditions. This would indicate that in the hot conditions there was no increase in the number of functioning glomeruli, even in the severely damaged kidneys.

Plasma Flow—The renal plasma flows (diodrast clearance) in normal and hypertensive subjects with

TABLE 4—Renal Plasma Flow in Patients with Normal Inulin Clearances

Subject	Diagnosis	Clearance* Cc					Hours Exposed
		Inulin		Diodrast		Variations	
		Comfortable	Hot	Comfortable	Hot		
R E	Normal	91	5	6	55	-2	3
L W	Normal	121	101	101	102	+10	2
L C	Essential hypertension (I)	107	101	110	77	-4	2
L F	Essential hypertension (I)	117	10	55	59	+31	0
R E	Essential hypertension (I)	111	6	70	73	+53	0

normal inulin clearances shown in table 4 are between the lower figures of 497 and 518 cc reported by White, Lindley and Edwards,³⁴ and the Chesleys,³⁵ respectively and the higher figure of 688 cc by Smith.⁴ When these patients were placed in hot conditions for two or three hours the changes in the renal plasma flow are not significant. The variations are in both directions and are not great.

Three patients with diminished inulin clearances (H W, A S and C V in table 5) showed a decrease in plasma flow which exceeded the ranges of experimental error when they were subjected to hot conditions. It is possible that the reduction in plasma flow may be associated with the somewhat longer exposure (four hours) to hot conditions than was practiced in the subjects with normal inulin clearances. It should be noted that in patients with sufficient kidney damage to cause definite reduction in inulin clearances there is no evidence of an increased blood flow under hot conditions.

Maximal Rate of Tubular Excretion of Diodrast—Of six studies (table 6) four were unchanged by the hot environmental temperature but two showed an increase. These increases occurred in 1 normal subject and one with mild hypertension. This finding would be of considerable importance if it could be regularly reproduced. Further studies are required on this point.

Tubular Resorption—A study of the oral fluid intake and volume of urine passed (table 7) indicates a significant decrease in the percentage of glomerular filtrate absorbed in these subjects with decreased inulin clearances and is another method of illustrating the decreased power of conservation of fluids in patients with "damaged" kidneys.

COMMENT

The magnitude of the transfer of blood from the interior to the surface under hot conditions as shown in table 3 subject L F amounts to 354 cc per square meter per minute or 611 cc of blood (plasma 342 cc) to 173 square meters of surface. It is realized that the interior vascular beds from which blood could be withdrawn are the lungs, viscera (liver, spleen) and muscles. Hence it is not probable that the kidneys

TABLE 5—Renal Plasma Flow in Patients with Diminished Inulin Clearances

Clearances Cc							
Subject	Diagnosis	Inulin		Diodrast		Variation	Hours Exposed
		Comfortable	Hot	Comfortable	Hot		
H W	Essential hypertension (1)	69	71	50	30	-18	4
A S	Essential hypertension (1)	69	86	41	46	-93	4
C V	Glomerulonephritis	19	19	170	103	-74	4
H M	Glomerulonephritis	16	14	120	79	-30	2

* Hot wet

would be called on to yield this entire 342 cc of plasma. If this quantity of plasma should be shunted from the kidneys it is obvious that their function would be severely impaired. It has already been shown³⁶ that the vital capacity of the lungs is increased in hot conditions and presumably this is due to a reduction in quantity of blood in this organ. The liver and muscles are capable of yielding appreciable quantities of blood.

The methods used for the measurement of plasma flow through the kidney have a probable accuracy of 10 to 15 per cent (50 to 75 cc). Hence the kidney might yield 75 cc of the 342 cc of plasma without our detecting it. In none of the experiments on kidneys with well maintained inulin clearances was there evidence of shunting of blood. In 3 of the patients with severely damaged kidneys there was slight detectable reduction in plasma flow which could have been shunted to the periphery. The whole experiment would justify the currently held view that the blood flow through the kidney is rather jealously guarded and not influenced to any great extent by other circulatory adjustments. They speak again for the autonomy of the control of renal circulation.

³⁶ Hick F K, Keeton R W, and Glickman Nathaniel. Physiologic Response of Man to Environmental Temperatures. Tr Am Soc Heating & Ventil Engineers 44: 145 1938

In previously reported experiments by Smith, it was noted that there was an increase in renal blood flow when pyrogenic substances were used even though the temperature was not actually elevated. The maximum rise in temperature under hot conditions in our cases amounted to 1.8 degrees F. Our data would indicate that slight rises in rectal temperature probably do not cause an increase in renal blood flow.

TABLE 6—Effects of Heat on Maximal Rate of Tubular Excretion of Diodrast

Subject	Diagnosis	Inulin Clearance		Diodrast Maximal Rate of Tubular Excretion		Hours Exposed
		Comfortable	Hot	Comfortable	Hot	
L C	Normal	103	96	47	70	4.0
J W	Essential hypertension (1)	108	110	44	39	4.0
D W	Essential hypertension (1)	101	87	47	44	4.0
A S	Essential hypertension (1)	107	95	20	21	4.0
C V	Glomerulonephritis	22	20	6	6	4.5
L S	Glomerulonephritis	9	6	11	7	2.0

These experiments have certain therapeutic implications. The applications of warm packs and heat in various forms are of no therapeutic value in promoting an increase in blood flow through the kidneys. In the previous discussion it was shown that the theoretical considerations would lead one to expect a reduction rather than an increase in the blood flow. In the severely damaged kidneys where therapeutic help is most desirable it is noted that the blood flow decreases rather than increases. In only two experiments (diodrast maximal rate of tubular excretion L C and J W) was there an increase in tubular mass. This subject deserves further study.

CONCLUSIONS

When patients were studied successively in comfortable and hot environmental conditions, the following changes were noted:

1 The increases in the peripheral blood flow in patients with hypertension and glomerulonephritis were the same as in normal subjects.

2 The inulin clearances in all experimental subjects remained unchanged.

TABLE 7—Tubular Resorption

Subject	Intake	Glomerular Filtrate Cc	Filtrate Absorbed per Cent
L W	1 100	122	99.3
S R	1 100	107	98.6
H W	1 000	69	98.4

C V	1 000	22	68.0
C V	1 000	19	76.6
L S	1 100	7	74.0

* Hot wet

3 The renal plasma flows in patients with well maintained inulin clearances show no change.

4 The renal plasma flows in patients with decreased inulin clearances show a slight but significant decrease.

5 The diodrast maximal rate of tubular excretion was found to increase in 2 of 6 cases studied.

Subjects with lowered inulin clearances are less able to conserve water than normal subjects, as indicated by a decreased percentage of the glomerular filtrate resorbed.

REPORT OF CASES

CASE 1—Normal control R E, a white man aged 37, complained of aching in his legs, weakness and palpitation for more than a year. The patient appeared to be in good health. Physical examination was essentially negative. The blood pressure was 108 mm of mercury systolic and 80 mm of mercury diastolic. Blood nonprotein nitrogen, urea nitrogen and uric acid were 35 mg, 101 mg and 3.3 mg per hundred cubic centimeters respectively. Urea clearance was 86 cc (maximal clearance). The basal metabolic rate was minus 14 per cent. Urinalysis was negative.

CASE 2—Normal control L W, a white youth aged 20, was studied on the fourteenth day following a hemorrhaphy. The blood pressure was 110/70. Urinalysis was negative.

CASE 3—Normal control L C, a white boy aged 14 years, was admitted to the hospital because of a *Typhoid* infection. He had scarlet fever as a child. He appeared in good health. The blood pressure was 122/80. Blood counts were normal. The urine contained an occasional pus cell. The blood nonprotein nitrogen was 297 mg per hundred cubic centimeters. Renal function tests followed excretion of the entire worm by one week. The diagnosis was *Typhoid* infection.

CASE 4—Essential hypertension S R, a white man aged 21, complained of palpitation and nervousness "most of his life." A hypertension had been noted three years previously on a routine examination, and recently he had been rejected from army service because of this finding. The patient appeared in good health. His blood pressure was 158/98 on admission to the hospital. Ocular fundus examination revealed grade 1 hypertensive retinopathy. Urinalysis was negative. Blood nonprotein nitrogen and urea nitrogen were 327 mg and 135 mg per hundred cubic centimeters respectively. Urea clearance was 648 cc (maximal clearance). Maximum urinary specific gravity was 1.029. The phenolsulfonphthalein excretion was 50 per cent in forty-five minutes. Hourly blood pressure readings for a twelve hour period varied from a low recording of 130/90 to a high one of 152/96. Sodium amylal caused a fall in blood pressure from 134/84 to 122/82. The cold stimulus test showed an elevation of 34 mm of mercury systolic and 20 mm diastolic. Cardiac size was normal. There was a low diphasic T_2 noted in the electrocardiogram.

CASE 5—Essential hypertension D W, a white youth aged 20, complained of some shortness of breath, dizziness, weakness and nervousness for one and one-half years. He had been found to have a hypertension by his family physician to the extent of 190 mm of mercury systolic. The patient appeared in good health. His blood pressure on admission was 148/70. Ocular fundus examination revealed a grade 1 hypertensive retinopathy. Urinalysis was negative. Blood nonprotein nitrogen was 367 mg per hundred cubic centimeters. The urea clearance was 88 cc (maximal clearance). The urogram was normal. Phenolsulfonphthalein excretion was 30 per cent in fifteen minutes. The cold stimulus test produced a rise in blood pressure from 144/84 to 152/92. Hourly blood pressures on a twelve hour bed rest regimen showed a range in readings from 134/70 to 158/80. Sodium amylal caused a fall in pressure from 160/66 to 116/70. The heart was normal in size and the electrocardiogram showed some right ventricular preponderance. Maximum urinary specific gravity was 1.038.

CASE 6—Essential hypertension R L, a Mexican girl aged 16 years, complained of headaches, vomiting and diplopia for one week before admission. The past history included tuberculosis of the spine. Examination revealed findings consistent with a diagnosis of right internal carotid aneurysm. The blood pressure was 146/104. The urine contained occasional granular casts. The ocular fundi revealed grade 3 hypertensive retinopathy. Intravenous urogram showed a small but otherwise normal left kidney. Maximum urinary specific gravity was 1.009. An intravenous injection of pentothal sodium caused a drop in blood pressure from 138/98 to 118/88. The urea clearance was 439 cc per minute (maximal clearance). The blood nonprotein nitrogen was 25 mg per hundred cubic centimeters. The phenolsulfonphthalein excretion was 15 per cent in fifteen minutes. The cardiac size was normal. The electrocardiogram showed ST_1 and ST_2 elevated and T_2 inverted.

CASE 7—Essential hypertension L F, a white youth aged 17 years, was referred to the dispensary because of a blood pressure found elevated to 210/130 on some routine physical examination. A study in the genitourinary clinic using intravenous and retrograde urography revealed a deformity of the right renal pelvis. There was a history of an injury to his right side at the age of 9 following which the patient had had gross hematuria. Examination revealed a blood pressure of 192/120. On admission to the hospital his urine contained 4 plus albumin (hecat-acetic acid test), occasional casts, pus and red cells. However, this test was not long after he had had a cystoscopic examination and a few weeks later, his urine contained only 1 plus albumin and an occasional cast. The blood nonprotein nitrogen was 36 mg per hundred cubic centimeters. The urea clearance was 58 cc (maximal clearance). The maximum urinary specific gravity was 1.025. The ocular fundi showed a grade 1 hypertensive retinopathy. Hourly blood pressures on a twelve hour bed rest regimen showed a range from 188/124 to 160/102. Sedative drugs caused a fall in pressure from 210/110 to 168/100. The cold stimulus test caused a rise in pressure from 188/120 to 212/140. The cardiac size was normal. Electrocardiographic findings included inverted T_1 , QRS, low and quadruphasic, T_2 and T_3 sharply inverted, ST_1 elevated, T_1 high.

CASE 8—Essential hypertension H W, a white woman aged 27, complained of headaches, tiring easily, nervousness and palpitation. The patient appeared in good health but seemed quite apprehensive. Her blood pressure was 222/138. A chest roentgenogram revealed localized densities in the right apex which represented an old tuberculous lesion. The ocular fundi showed a grade 1 hypertensive retinopathy. The urine was normal. The phenolsulfonphthalein excretion test was 45 per cent in fifteen minutes. The urea clearance was 606 cc (maximal clearance). The maximum urinary specific gravity was 1.030. During a twelve hour period of bed rest the hourly blood pressures varied from 184/128 to 260/150. Sodium amylal caused a fall in pressure from 244/144 to 156/106. The change under sodium nitrite was very similar. The cold stimulus test caused a rise of 20 mm of mercury systolic and 7 mm diastolic. The intravenous urogram was normal. The electrocardiogram revealed an inverted T_1 and the heart size was normal. The blood nonprotein nitrogen was 33 mg per hundred cubic centimeters.

CASE 9—Essential hypertension A S, a white woman aged 33, complained of shortness of breath on exertion, headaches, dizziness and some precordial distress for one year. Late in her second pregnancy, one year previously, her blood pressure rose to 160/110. She appeared in good health on the present admission to the hospital. The ocular fundi showed a grade 1 hypertensive retinopathy. The blood nonprotein nitrogen was 30 mg per hundred cubic centimeters. Urine studies were negative. The urea clearance was 43 cc (maximal clearance). The phenolsulfonphthalein excretion was 30 per cent in fifteen minutes. The maximum urinary specific gravity was 1.030. During a twelve hour period of bed rest the hourly blood pressures varied from 130/80 to 172/108. Under sodium amylal the blood pressure fell from 148/90 to 122/70. Sodium nitrite caused a fall of 16 mm systolic and 6 mm diastolic. The cold stimulus test caused a rise of 20 mm systolic and 22 mm diastolic. The heart size was normal. The electrocardiogram revealed left ventricular preponderance.

CASE 10—Essential hypertension J W, a white man aged 24, complained of weakness, dyspnea on exertion, joint pains, a postnasal drip and maxillary sinusitis. The patient had had rheumatic fever at the age of 12 and again at the ages of 16 and 17. Recently his family physician had noted a hypertension of 185/120. On admission to the hospital he was ambulatory and appeared in good health. His blood pressure was 158/88. The thyroid gland was somewhat diffusely enlarged. There was a loud systolic murmur heard over the apex. The basal metabolic rate was minus 6 per cent. The erythrocyte sedimentation rate was 10 mm per hour corrected. The blood cholesterol was 210 mg per hundred cubic centimeters. The blood nonprotein nitrogen was 347 mg per hundred cubic centimeters. The urea clearance was 37 cc (standard clearance). The phenolsulfonphthalein excretion was

10 per cent in fifteen minutes. The ocular fundi showed a grade 1 hypertensive retinopathy. Sodium amytal caused a fall in pressure from 160/90 to 118/80. Sodium nitrite caused a drop of 18 mm systolic and 10 mm diastolic. Cold stimulus test caused an elevation of 16 mm systolic and 36 mm diastolic. The electrocardiogram showed inversion of T_2 . The heart size was normal. The urogram was normal and the maximum urinary specific gravity was 1034.

CASE 11—*Chronic glomerulonephritis*. L. S., a white man aged 35, complained of itching and pigmentation of the skin for nine months and weakness for one year. His past history was irrelevant. He appeared anemic and showed a peculiar light bronzed-like appearance of the skin. He was amblyopic. His blood pressure was 110/70. The erythrocyte count was 15 million per cubic millimeter and there was 5 Gm of hemoglobin per hundred cubic centimeters (Sahli). Urinalysis was negative. The blood nonprotein nitrogen, urea nitrogen and creatinine were 128.6 mg, 85.5 mg, and 9.1 mg per hundred cubic centimeters respectively. The carbon dioxide combining power was 30 cc per hundred cubic centimeters of plasma. Serum proteins were normal and the icterus index was 7 units. The ocular fundi were normal. The urea clearance was 5 cc per minute (standard clearance). The cardiac size was normal. The intravenous urogram was unsatisfactory because of the failure of the diodrast to be excreted in a quantity sufficient to cause visualization.

CASE 12—*Chronic glomerulonephritis*. H. M., a white woman aged 23, complained of headaches, occasional vomiting and some pain in her lumbar region for one year. She had been told previously that she had hypertension. Symptoms started with her first pregnancy one year previously when she had had toxemia associated with her pregnancy. Examination revealed a blood pressure of 184/114. Urinalysis showed 4 plus albuminuria (heat-acetic acid test), an occasional granular cast and pus cell but no erythrocytes. The urea clearance was 16 cc (maximal clearance). The blood nonprotein nitrogen, urea, acid and creatinine were 54.7 mg, 34 mg, 53 mg, and 4.5 mg per hundred cubic centimeters respectively. Intravenous urograms showed unusually small kidneys bilaterally. Ocular fundus examination revealed a grade 2 hypertensive retinopathy. Cold stimulus test caused a rise in blood pressure from 182/120 to 208/172. Sodium amytal caused a fall in pressure from 174/116 to 142/100.

CASE 13—*Chronic glomerulonephritis*. R. R., a white woman aged 22, complained of backaches, headaches, dizziness, some swelling of her face and ankles and slight visual disturbances for one year. Her past history indicated some kidney trouble at the age of 3 years, at which time she had been seen by a "kidney specialist." One year prior to admission she was told she had pus and albumin in her urine. Urinalysis revealed 3 plus albuminuria (heat-acetic acid test) and an occasional pus cell but no erythrocytes or casts. There was poor visualization of the urinary tract by intravenous urography. A right retrograde pyelogram showed questionable pyelectasis with blunting of the calices. There was essentially no response to the cold stimulus test except in the diastolic pressure which rose 16 mm of mercury. Hourly blood pressure readings during twelve hours of bed rest varied from 130/82 to 150/110. Sodium amytal caused a fall in pressure of approximately 14 mm of mercury systolic. Sodium nitrite caused a fall of 22 mm systolic and 12 mm diastolic. The urea clearance was 22.3 cc (maximal clearance). The phenolsulfonphthalein excretion was 15 per cent in fifteen minutes. The blood nonprotein nitrogen was 42 mg per hundred cubic centimeters. Cardiac size was normal, as was the electrocardiogram.

CASE 14—*Chronic glomerulonephritis*. C. V., a white man aged 30, complained of headaches and swelling of his feet and eyelids for several months. He had had scarlet fever at the age of 20. At the age of 24 and several times thereafter he had had gross hematuria. In 1940 he had definitely swollen ankles. Examination revealed a blood pressure of 196/124. There was a 4 plus albuminuria (heat-acetic acid test), occasional granular and hyaline casts, erythrocytes and pus cells. Ocular fundus examination revealed a grade 4 hypertensive retinopathy. Urea clearance was 21 cc (standard clearance).

Blood nonprotein nitrogen was 44 mg per hundred cubic centimeters. Serum albumin was 23 per cent and serum globulin was 17 per cent. Sodium amytal caused a fall in blood pressure from 190/124 to 142/116. The cold stimulus test caused a rise of 44 mm systolic and 16 mm diastolic. Heart size was normal.

ABSTRACT OF DISCUSSION

DR BENJAMIN JABLONS, New York. I have studied effects on renal blood flow by means of a different approach. This consisted in explanting the kidney subcutaneously and externally. Thus, temperature changes in the kidney could be determined under the influence of various environmental and local as well as indirect temperature modifications. In rabbits and dogs the kidney was exteriorized, so that temperature changes could be determined directly by the application of a thermocouple to the exposed surface of the kidneys. Dogs, in which exteriorization did not prove as practicable as it did in rabbits, were studied by means of a subcutaneous thermocouple. Environmental temperature changes produced little effect in the exteriorized kidney of the rabbit. In the dog, the application of cold or heat directly over the skin covering the surface of the explanted kidney failed to influence the temperature change in any great degree. Immersion of the hind legs in cold water produced little change. However in 1 dog (that was hypertensive) with one kidney explanted and one kidney removed we found that the use of hot packs did seem to change the temperature about 1 to 2 degrees C. However, if the hind legs were immersed in water the kidney temperature changed but little. Another point observed was that in the kidneys which were exteriorized the kidney temperature remained much the same on a hot day as when the temperature was much reduced. In the main these findings are in agreement with the experience reported by the authors.

Clinical Notes, Suggestions and New Instruments

A FOREIGN BODY FINDER THE LOCATOR

JOHN J. MOORHEAD, M.D., NEW YORK

There has always been difficulty in accurately locating metallic fragments embedded more or less deeply in human tissues. For decades many devices have been tried most of them based on the principle of the magnet. Some of these were designed so that a sound effect or a light effect gave added information. Many variations of roentgen triangulation have also been used. However, few of these provided substantial help until the operative zone was uncovered, but thereafter in many cases these magnetic devices failed to act because of the interposition of the body fluids or tissues. So called telephone probes and allied instruments were useful only within certain limits. In World War I the Bergonie apparatus was probably used more satisfactorily than any other, but it was very bulky (about the size and shape of a flower pot) and often failed when the embedded fragment was small.

Practically all these devices functioned only for iron or steel and unfortunately many foreign bodies are of the nonmagnetic type notably lead. X-ray and is obviously of great value, and to the ordinary film many accessories and markers have been added more positively to delineate the hidden object. Nevertheless in many cases the search is prolonged and fruitless even though the films had been carefully prepared and skillfully interpreted. In civilian as well as in military experience there was real need for some device that would act in association with or independent of X-ray aid.

Such a device should locate the object accurately prior to the operative exposure and be equally effective in determining the depth in the wound. It should give a visible response on the dial or other indicator and become activated by fragments of iron, steel, copper, silver, aluminum, lead or thir-

combinations. Likewise, the electrical source should be of the ordinary plug in type or come from a storage battery or dry cells. Such elements as cost, size, sturdy construction and portability were also involved.

An apparatus fulfilling many of these requirements has been perfected and is in production.¹ It is called the 'Locator' and was devised for me by Samuel Berman of the electrical engineering department of the New York City Transit System. After more than a year of experimentation the first trial of the apparatus was made by me in November 1941 at the Reconstruction Hospital Unit of the Post-Graduate Hospital on a police officer who had been one of the victims in the bomb explosion at the New York World's Fair in July 1939. Several metallic fragments were removed from the region of the patient's ankle and purposely, so that an extreme test might be made, no x-ray aid was employed.

I took this apparatus with me to Honolulu in December 1941 to demonstrate it before a group of physicians who had invited

Appearance and dimensions of the Locator

me to give a series of lectures on traumatic surgery. The first mass usage of the device was at Tripler General Hospital at the time of the Pearl Harbor attack, where I returned to army duty as Colonel, Surgical Consultant. At this U. S. Army hospital many of the surgical personnel used the locator with great success and indeed on two successive days removed 21 embedded fragments without a single failure.

While there, my own most satisfactory experience with the locator was in the removal of a machine gun bullet lodged within the spinal canal at the upper lumbar level, and without this "diviner" it is doubtful whether the missile would have been found despite the accurate localization afforded by many roentgenograms. The original apparatus was left at this hospital, and since returning I have used successive improved models successfully in several civilian cases.

The general appearance of the locator in size and shape suggests a portable radio. On the front panel are the dial (A) to record the proximity of the object and a single control knob (B) for regulating the sensitivity of the apparatus. The probe or finder (C) is the size and shape of a large fountain pen; it is made of stainless metal or bakelite and is furnished with a sterilizable, specially fitted rubber sleeve for search within the

wound. In an emergency a rubber glove or towel or other sterilizable material may be used instead. The plug in wire (D) is like that of any radio. A 20 foot ground wire with a spring clip terminal (E) is connected to eliminate body capacity effects and static charges.

To use the apparatus, the probe or finder is passed over the suspected area and the movements of the needle on the indicator dial are observed. As the probe comes closer to the metal particle, the needle moves higher on the dial scale until the point on the surface is found which gives the highest reading. This gives the skin or surface location and to some degree denotes also the size and composition of the metal. However, it is also necessary to know the subsurface depth, and to obtain this I select a piece of metal of the same composition and the approximate dimensions as shown on the x-ray film and approach the probe with it until the dial reading is the same as the reading previously noted on the surface location on the patient's body. The distance between the test object and the probe then equals the subsurface depth. This determination is exceedingly accurate and will usually not vary more than $\frac{1}{32}$ inch. The fact that in the surface location there was intervening tissue while in the case of the comparison reading with the test object the measurements were in air is entirely immaterial because human tissue and air have practically identical permeability to magnetic lines of force.

If when the incision is made the foreign body is not immediately discovered the probe (covered with its sterile sleeve) is placed in the wound and moved lengthwise with respect to the incision to a point at which the highest reading is obtained. Then the probe is pressed against each of the two walls of the incision in turn to determine by the higher of the two readings which wall contains the foreign body. The probe is then slowly raised and lowered and is stopped at the depth which gives a maximum reading on the indicator dial. In this way the correct direction in which to proceed is accurately ascertained. Obviously all metallic instruments are laid aside while the search proceeds. Wooden tongue depressors or plastics can be used for temporary retractors.

The probe handle has a control by which the operator can at will make most of the necessary adjustments without requiring an assistant at the instrument panel. There is a pilot light to show when the instrument is in use.

An apparatus working on similar principles has been used to locate buried ores or metals. The relative sensitivity of the locator to the various metals is in the order named: iron, steel, silver, copper, gold, aluminum, magnesium, platinum, lead.

So far as I know, there is no identical device although in Great Britain and in Germany² foreign body devices of a new design are said to be in use. Some of these are x-ray adaptations, others are superheterodyne modifications.

This locator was recently used at the New York Post Graduate Hospital to extract a metallic fragment (approximately $\frac{1}{4}$ by $\frac{1}{8}$ by $\frac{1}{2}$ inch) from the front of the lower third of the thigh where it presumably lay close to the bone. The surface location and depth extent were easily registered, but it required four insertions of the probe before the surgical route was determined sufficiently to extract the fragment without enlarging the original external incision. It is quite certain that I would have failed without the aid of this device. On another occasion a small foreign body was removed from the deltoid region after two previous vain attempts had been made elsewhere. Concededly in many cases it is entirely unnecessary to extract a foreign body in a silent or inaccessible region. However, the possessor of even a tiny fragment is often unwilling to permit it to remain for fear that "it may wander." Such anxiety is usually unwarranted, because an embedded fragment almost

irregularly remains in situ, imprisoned in scar tissue which usually appears very promptly. Within cavities the wandering tendency of lost instruments is of frequent occurrence, as for example in the abdomen, where artery clamps and the like are sometimes found quite distant from the operative zone, and the locator in such cases may be useful.

In the civilian as well as in the war zone this apparatus appears to have the following advantages:

- 1 Portability combined with sturdy construction and adaptability to any electrical source
- 2 Ability to be used as an accessory to fluoroscopy and to x-ray films or without them
- 3 Susceptibility of being used within the wound
- 4 Responsiveness to many kinds of metals
- 5 Ease and certainty of application

SCHISTOSOMIASIS INFECTION REPORT OF TWO CASES FOUND IN NORTHERN MICHIGAN

BENJAMIN B. BLUM, M.D. AND HARRIS V. LILGA, M.D.
PETOSKEY, MICH.

We record here 2 cases of *Schistosoma hematobium* infection found in northern Michigan. The widespread migration resulting from conditions associated with the war will introduce into the United States and Canada diseases endemic in foreign countries. Unless possible occurrence of tropical disease is considered, wrong or missed diagnoses will be inevitable. People who have spent much time in the tropics are apt to be more familiar with some tropical diseases than many physicians in this country.

Schistosomiasis is endemic chiefly in the Mediterranean countries, the Near East and over most of Africa and nearby islands. A review of the etiology, pathogenesis, symptomatology and treatment would appear superfluous at this time since they are adequately described in all modern textbooks of tropical medicine.

The majority of reported cases in this country have been well advanced and diagnosed relatively late in the course of the disease. As far as we have been able to learn from the literature, there have been no cases reported in this country which had been diagnosed prior to the onset of symptoms. Manson¹ states that the incubation period ranges from three months to two and a half years. Our cases are consistent with this observation. Most cases of schistosomiasis reported in this country have been concerned with *Schistosoma hematobium*. *Schistosoma mansoni* has been found by Hoff² in New York, and *Schistosoma japonicum* has been reported from New Orleans by Hauser.³

The cases reported here are examples of a definitely known incubation period. So far as we have been able to determine case 2 is the only case in this country diagnosed prior to the development of symptoms.

REPORT OF CASES

CASE 1—A white boy aged 9 years seen March 25, 1942, complained of bloody urine for the past three months and enuresis for two days. He stated that for the past three months he had noted a small amount of blood at the end of urination. At first this appeared every three to four days, but in the past week it had occurred daily, the blood being seen usually at the midday urination. There was no history of recent

infection or injury. In other respects he appeared to be in good health. The boy was born in South Africa where his parents had been missionaries. The mother stated that there were many rivers in this part of Africa which were infected with snails. Approximately a year before admission the boy had swum in a river near Durban, Natal, on the East coast of Africa. He had not been swimming in natural waters in Africa at any other time. The family returned to the United States in June 1941. Since that time they had lived in northern Michigan.

The boy was moderately thin, was 55½ inches (141 cm) tall and weighed 63 pounds (28.6 Kg). The temperature was 98.8 F, the pulse rate was 92 beats a minute and the blood pressure was 96 systolic and 62 diastolic. The only demonstrable physical abnormality was a slight tenderness in the right renal area.

The laboratory studies showed a hemoglobin of 81 per cent (13.4 Gm) and an erythrocyte count of 4,100,000, giving a color index of 0.99. The hematocrit determination showed a volume index of 1.2. The leukocyte count was 11,400, with a differential count of neutrophils 50 per cent, lymphocytes 48 per cent, basophils 1 per cent and monocytes 1 per cent. Subsequent differential counts showed as high as 11 per cent eosinophils. Urine specimens were normal except for the terminal few drops, which showed numerous pus cells and erythrocytes and numerous colonies of *Staphylococcus aureus*. The blood urea was 10 mg per hundred cubic centimeters and the Kahn precipitation test for syphilis was negative.

On the basis of these findings he was treated with sulfathiazole. In two weeks the pyuria had disappeared and urine cultures became negative. However, the terminal bleeding persisted. Because of his having lived in a region in which schistosomiasis is endemic, a search for *Schistosoma* was made repeatedly on the terminal portion of urine specimens until a typical ovum of *Schistosoma hematobium* was discovered four weeks after the patient was first seen. The appearance of the ovum is shown in the accompanying illustration.

Because of the finding of *Schistosoma*, urine and stool examinations were done on the rest of the family—the parents, two sisters and one brother. The findings were negative in all but the brother.

CASE 2—Ova were isolated in the urine of the 12 year old brother on April 25, although he had had no symptoms and had appeared to be in good health. However, on May 8 terminal hematuria first appeared. He had been swimming with his brother in the Njongwane River in Natal, South Africa, in January 1941 and had been on several walking trips, crossing some of the smaller streams.

The boy was healthy appearing, was 64½ inches (164 cm) tall and weighed 104 pounds (47 Kg). The temperature was 97.2 F, the pulse rate was 80 beats a minute and the blood pressure was 114 systolic and 74 diastolic. The laboratory findings were a hemoglobin of 77 per cent (12.8 Gm), an erythrocyte count of 3,780,000 and a leukocyte count of 7,000, with 36 per cent lymphocytes, 44 per cent neutrophils and 20 per cent eosinophils. Several urinalyses were negative, except for the presence of both pus cells and erythrocytes varying from 1 plus to 4 plus and demonstrable ova of *Schistosoma hematobium* in most specimens. The urine culture showed 15 colonies of *Staphylococcus aureus* to 0.5 cc of urine. The blood urea was 17 mg per hundred cubic centimeters and the Kahn precipitation test for syphilis was negative. The patient was not given any treatment for the staphylococci in the urine.

TREATMENT

Intramuscular injections of fuadon were started on both patients. Each was given an injection in the gluteal muscles of 0.5 cc the first day, 1.5 cc the second day and thereafter

From the Burns Clinic.

2. Hoff, Amanda. *Schistosomiasis*. Report of Two Cases. J. A. M. A. 107: 1375-1378 (Oct. 24) 1936.
3. Hauser, G. H. *Schistosomiasis*. Report of a Case. New Orleans M. & S. J. 92: 265-270 (Nov.) 1939.

35 cc was given until a total of 30 cc (19 Gm) had been given. The ova continued to appear in the urine until two weeks after fuadin was started, then no further ova were found.

Except for mild muscular pain at the site of the injections no local or systemic reactions occurred. Supplementary treatment was not given. The family then moved to southern Michigan, from where the mother of the patients reported to us that a second course of fuadin had been given to the younger boy because of a recurrence of ova in the urine. According to reports from the mother there has been no further evidence of the disease up to September 1942.

COMMENT

According to a survey of the available literature the 2 cases reported by us bring to 33 the total number of cases found and reported in the United States and Canada. Of these the only case previously reported in Michigan was that of Campbell⁴ in 1938. Apparently the only instance of the disease occurring in a person who had never been in a country in

Ovum of *Schistosoma hematobium* ($\times 800$)

which the disease is endemic is the case reported by Sullivan⁵. The infection in this instance was apparently acquired by the patient's playing with an aquarium stocked with Egyptian snails.

A possible second exception is the case reported by Peacock and Voegtlin⁶ in which the patient died of heart disease the day after the diagnosis of schistosomiasis was made.

There appears to be little reason to fear that any cases except those brought into this country will occur. It is believed that there is no intermediate host in this country such as the special snails found in the region in which the disease is endemic.

SUMMARY

The two cases of *Schistosoma hematobium* infection here presented are, we believe, examples of a diagnostic and therapeutic problem requiring the alertness of civilian physicians, since one may logically anticipate many cases of chronic diseases endemic in foreign countries in the next few years.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE
HOWARD A. CARTER, Secretary

THE THERAPEUTIC VALUE OF ULTRAVIOLET RADIATION

(Continued from page 623, volume 120)

INDOLENT WOUNDS

In certain cases of indolent ulcers and wounds occasional erythema doses of ultraviolet radiation or daily treatment with graduated doses of solar radiation or artificial ultraviolet rays seem to be helpful. Some indolent ulcers and wounds appear to respond rapidly and favorably to both solar and artificial ultraviolet radiation. On the other hand ulcers occurring in Raynaud's disease or in thromboangiitis obliterans and also old chronic varicose ulcers do not respond to ultraviolet radiation.

CRYSPELS

Good results have been obtained in crabs with both x rays and ultraviolet rays. Recently many reports have appeared in the literature which show that ultraviolet radiation is a safe and successful method for the treatment of crabs, especially in the very young and the old. Many times the erythema dose (eight to twenty) of ultraviolet rays from a quartz mercury arc generator is applied at one sitting to the diseased area including an inch or two of the normal surrounding skin. The treatment is repeated a second or a third time and if necessary a fourth or fifth time on successive days. Since crabs responds so well in all ages to the sulfonamides, ultraviolet radiation is being used less frequently. The sulfonamides are photosensitizing drugs. Therefore they should not be used in conjunction with ultraviolet rays.

IMPOT

While irradiation with ultraviolet may have some effect on secondary impotency, this effect is limited and not specific and far less efficient than dietetic and drug treatment.

Intense ultraviolet radiation may result in abnormal white blood cell counts. There is no unequivocal evidence that ultraviolet radiation increases resistance to specific or general infection, although a relation ship between sunlight and the general course and character of disease, growth and nutrition has been demonstrated.

BLOOD PRESSURE

From a clinical standpoint the claim that ultraviolet rays reduce blood pressure has not been sufficiently established by the majority of those who have had long experience with natural or artificial heliotherapy to command acceptance. Most investigators feel that while exposure of the entire body to ultraviolet rays may produce some reduction in blood pressure in certain individuals, this reduction is too light and inconstant to be of clinical value. The lowered blood pressure of persons living in the tropics is the result of the action of a number of characteristics racial mode of life, meteorological conditions and their changes and cannot be correlated with the quantity and quality of radiation.

DERMATOSIS

It appears to be the general impression in the medical profession and among lay persons that ultraviolet irradiation is of great value in dermatology. However, most of the therapeutic claims have not been corroborated and may be disregarded. There is sufficient evidence to justify the belief that ultraviolet radiation is a valuable remedy for crabs and for certain types of cutaneous and subcutaneous tuberculosis. It is reasonably well established that ultraviolet radiation is at times useful either alone or as an adjunct for the treatment of acne vulgaris, adenoma sebaceum, pityriasis rosea, psoriasis, psoriasis telangiectatica, indolent ulcers and wounds. While there is some difference of opinion among dermatologists, the majority while admitting occasional good results that appear to be due to the radiation do not consider it an important agent in the management of other disorders.

7 MacKee and Cappelaro. Ultraviolet Therapy in Dermatology. In a book of Physical Therapy, ed. 3, pp. 333-358.

Some physicians believe that ultraviolet radiation improves the color and texture of the complexion. Such statements are not in agreement with the consensus of dermatologic opinion.

Diseases Due Partially or Wholly to Pyogenic Organisms—Acne Vulgaris. At least 60 per cent of the patients can be cured with conventional dermatologic therapy in from a few months to a year without recourse to ultraviolet therapy. Such treatment embraces the proper choice of topical applications, adequate instruction and advice, attention to hygiene and diet and attention to various possible internal disturbances.

Erythema or flushing doses of artificial ultraviolet radiation or solar radiation once or twice a week, or daily if toleration is high, will very often cause the eruption to improve or disappear, but unfortunately recurrence is the rule. Rapid temporary improvement in selected cases is obtained often by producing an acute reaction followed by desquamation. Most dermatologists agree that the radiation is a useful adjuvant when treating recalcitrant cases. In such instances it supports topical remedies and other conventional measures. It may be combined with x-rays but if so, it is advisable to avoid erythema.

Acne vulgaris is divided into a number of clinical varieties. The intelligent management of the disease requires a clinical knowledge of the various types because the therapeutic indications differ somewhat with the type. Acne indurata is the common type. It is encountered mostly in late adolescent and early adult life and is chronic in course and appearance. In addition to comedones, pustulous follicular orifices and scars there are numerous large, deep seated pustules and perhaps occasional indolent cystlike lesions. The skin is likely to be excessively oily. This type usually tolerates and responds well to vigorous treatment.

The more acute types—acne pustulosa and acne erythematoza—are more likely to be associated with detectable and correctable systemic disturbances. It is advisable to begin treatment with soothing topical remedies before resorting to physical therapy.

Comedo and acne papulosa are seen most often at puberty. The lesions consist of blackheads and papules and there may be also some pustules and an oily skin. At times these types disappear spontaneously or yield quickly to stimulating topical remedies. Not infrequently, however, it is impossible to cure the puberty cases permanently until the patient is somewhat older. It is possible as a rule, to control the disorder through this period with suitable topical remedies or with ultraviolet radiation or both. It is important to do so otherwise acne indurata, oily seborrhea, scars and a coarse skin are apt to develop.

Although ultraviolet radiation has been blamed for superfluous hair in cases of acne vulgaris, it is generally agreed that this agent cannot make hair grow on glabrous skin. Hystriochosis in association with acne vulgaris has been noted in the absence of local treatment of any kind. However when girls and women have a tendency to grow hair on the face it is theoretically possible that the frequent application of any remedy producing hyperemia might encourage the growth.

Rosacea and Rhinophyma. Rosacea can almost always be cured by giving adequate attention to the internal causes combined with suitable topical remedies. Irradiation is of little if any value. Ultraviolet radiation is usually not well borne although it may be of service in an occasional selected case. So far as concerns local treatment, the best results in cases of hypertrophic rosacea and rhinophyma are obtained with multiple scarification, surgical diathermy and scalp surgery.

Acne Varioliformis. Ultraviolet radiation is of doubtful value.

Sycosis Vulgaris. Ultraviolet radiation appears to have very little effect on the disease. Under the heading of sycosis may be included chronic pustular folliculitis of the bearded region of male adults, the eyebrows, the scalp and the pubic region. In such cases general body irradiation with solar or artificial ultraviolet radiation may be tried, but there is no real evidence that such treatment is of value.

Furunculosis and Carbunclosis. Many physicians believe that an erythema or a blistering dose of ultraviolet radiation preferably with a water cooled lamp with compression when applied to a boil in the very early stage of evolution, will either abort the lesion or greatly modify further development. In the hands

of most dermatologists this procedure has been uncertain and disappointing. Recurrent boils indicate some constitutional fault—organic functional or immunologic—which must be corrected if possible. In such instances it is possible that a long course of general body irradiation using either the sun or an artificial source of light might prove beneficial. While the general impression is that such treatment is helpful there is no conclusive evidence that this is so.

Miscellaneous Pyogenic Disorders. Ultraviolet ray treatment or heliotherapy may be of service in cases of acne conglobata (acne cacteticorum) but the result is usually disappointing. Good results have been reported with ultraviolet radiation in cases of perifolliculitis capitis abscedens et sufficiens, but the evidence is insufficient for an evaluation.

Diseases Due to Fungi. Many of the fungous dermatoses—blastomycosis, actinomycosis, onychomycosis—have been treated with ultraviolet radiation with poor results. Perleche a disease of the buccal commissures may be due to bacteria, fungi or to a deficiency of nicotinic acid or riboflavin. Ultraviolet radiation has not proved efficacious in this disease. Many eruptions due directly or indirectly to fungi and known as dermatophytosis and dermatophytid are discussed under the heading of eczema.

Eczema. It no longer suffices to say that a certain agent is of value in the treatment of eczema. Today the unqualified term eczema signifies inflammation of the skin (dermatitis) having certain characteristics that are not so frequently encountered in other eruptions. Each of the number of clinical types of eczema has a somewhat different cause and exhibits fairly definite characteristics. While the therapeutic indications are somewhat different for the various types, each clinical variety has certain features common to all.

Eczema venenatum (dermatitis venenata) is caused by external contact with a substance to which the patient has become sensitized. Well known examples are rhus dermatitis, dye dermatitis and trade eczema. Naturally the logical procedure is to ascertain and remove the cause. Ultraviolet radiation is not indicated in this type.

Dermatophytosis is a convenient term coined by Higginman to indicate eczema caused by fungi of which there are several types. To general practitioners and to the public these conditions are known as ringworm or 'athletes' foot.

The keratotic type occurs mostly on the palms and soles and consists as the name implies of a thickened horny layer. The interdigital and vesicular varieties are the common types of dermatophytosis. Ultraviolet radiation has been advocated but the results do not warrant its recommendation.

Infectious eczematoid dermatitis is a more or less generalized eczema that develops secondary to a discharging sinus, ulcer or wound. Ultraviolet radiation is also ineffective in this type.

Neurodermatitis occurs in two forms—circumscribed and disseminate. The circumscribed type (lichen chronicus circumscriptus) seen mostly in adults resembles patches of chronic lichen planus and shows a predilection for the flexures—the sides of the neck, the cubital and popliteal spaces and flexor surfaces of the thighs and for certain extensor surfaces—the elbows and knees—where it may exhibit a strong resemblance to psoriasis and the back of the neck in women (eczema nuchae). The Fox-Fordyce disease of the axillas and pubic region is probably a rare type of circumscribed neurodermatitis. Patches of circumscribed neurodermatitis range in size from a dime (18 mm) to an adult palm. A full erythema dose of ultraviolet radiation may be followed by improvement, but the results are uncertain.

The disseminate type of neurodermatitis when severe is one of the most recalcitrant and distressing of the dermatoses. It occurs for the most part in patients who give a personal or family history of allergic disorders—urticaria, hay fever, asthma—and the patient is often sensitized to a large number of substances—food proteins, epithelial products (hair dander, feathers), pollens and bacterial proteins. The neurogenic factor is prominent, and there may be endocrine dysfunction. The disease is common in infants, children and adolescents, less common in young adults and uncommon in older persons. There are acute exacerbations and remissions, both of which may be of short or long duration. Itching is likely to be almost intolerable.

There is a difference of opinion regarding the efficacy of ultraviolet radiation (general body irradiation) in neurodermatitis. Certainly many patients improve when they are able to indulge in heliotherapy, but it has been impossible thus far to determine whether the improvement is due to a combination of environmental factors (rest, relaxation, contentment, salt water bathing effect of moving air on the naked skin, change of climate, escape from causative proteins) or to ultraviolet radiation.

Only occasional good results are obtained with artificial ultraviolet radiation, and in these instances improvement might have been due to other factors. Many patients have a low tolerance for radiant heat and appear to be made worse with small doses of ultraviolet radiation. Amounts sufficient for erythema are likely to precipitate an exacerbation.

Eczema seborrheicum (dermatitis seborrheica) presumably a bacterial, rather polymorphous type of eczema in its most simple form may consist of dandruff, a few scaly patches on the face and ears, or excessive oiliness of the face and scalp. The more severe eruptions consist of exudative and crusted patches on the head, scaly patches and patches of follicular papules on the trunk, and erythematous scaly patches under pendulous breasts and in the pubic and crural regions. It is often difficult to differentiate between seborrhea, dermatophytosis and psoriasis. Occasionally ultraviolet radiation appears to give good results, especially erythema doses for chronic dry patches, but in general it may be stated that ultraviolet radiation has not been of much service in the management of this form of eczema.

Eczema hemostaticum (dermatitis hemostatica) generally occurs on the legs of elderly persons and is due primarily to poor local circulation caused by varicose veins, cardiovascular disturbances, renal inefficiency, tight circular garters and so on. Additional causes are scratching and infection with pyogenic organisms. The principal treatment consists in support for the circulation (elastic stockings) and the correction of constitutional disturbances. Ultraviolet radiation appears to be of benefit for the indolent ulcers that so often complicate the disorder and it may be of service when the skin is considerably thickened. On the whole, however, ultraviolet radiation is not efficacious for this type of eczema.

Intertrigo is an erythema occurring in locations where the parts are in contact (axillas, crural region) and is due to friction, heat and unhygienic conditions. Dermatitis, with edema, exudation and crusting, may develop (eczema intertrigo). Differentiation must be made from dermatophytosis. Ultraviolet rays have been used for recurrent eruption with questionable results.

The term infantile eczema signifies no more than eczema occurring in an infant. Usually such eczema is one of the enumerated types or a combination of two types. So far as concerns ultraviolet there are no special indications other than those found throughout the section dealing with eczema.

Many dermatologists claim that ultraviolet rays are useful for many varieties of eczema and in selected cases this is possibly true, but in general terms American dermatologists agree that ultraviolet radiation is not of much value in this disease. It is not indicated in acute eczema. General body irradiation may be of some value in selected cases of chronic eczema. At times, any agent that will evoke hyperemia in a patch of chronic squamous eczema will hasten recovery. Ultraviolet radiation may be used for this purpose, however, judgment is required or the condition is apt to get worse instead of better. Such treatment may be successful but the physician is taking a risk.

Psoriasis, *Parapsoriasis*, *Dermatitis Exfoliativa*, *Lichen Planus*. In psoriasis, ultraviolet radiation in amounts sufficient to cause erythema, applied to the individual lesions about once a week, will at times promote resolution. Such treatment, however, is not particularly efficacious and if the erythema involves the normal skin, the lesion may spread over the entire area of erythema.

Daily heliotherapy to the entire body irrespective of the location of the eruption or daily general body irradiation with artificially produced ultraviolet rays, is thought by many dermatologists to be of value. It is advisable to avoid erythema because the too vigorous treatment of psoriasis, especially the more acute types, may favor the development of dermatitis

exfoliativa. In fact, radiation is contraindicated in the acute types. If general body irradiation is proved to be of real value, it would seem to be a particularly favorable treatment for children. Goeckerman and O'Leary's coal tar technique appears to have given better results in psoriasis than the use of ultraviolet radiation alone. This consists in applying a 3 per cent crude coal tar ointment at night. The next morning the ointment is wiped off. This is followed by irradiation of the entire body after which a bath may be taken. When possible, the treatment is given daily. The most that can be hoped for in psoriasis is control of the disease, it cannot be cured.

Remissions in parapsoriasis in incurable disease, have been reported with erythema doses of ultraviolet radiation. There are several types of the disease only two of which have at the present writing responded temporarily to the treatment—the papular and the plaque or patch types.

Ultraviolet radiation has not been found useful in dermatitis exfoliativa.

Pruritus. *Prurigo*.—Ultraviolet radiation is recommended by some for the various types of essential pruritus—pruritus ani, pruritus vulvae, so called senile pruritus—but the majority of dermatologists have not been favorably impressed with the results. Erythema doses may increase the pruritus.

Ultraviolet rays have been advocated for the relief of pain associated with diseases such as zoster. They appear to be of little service for this purpose.

Prurigo nodularis does not yield well to ultraviolet rays, although a few apparently satisfactory reports have been published. The same statement applies to prurigo nitis and prurigo ferrox.

Diseases of the Appendages.—In hyperhidrosis, ultraviolet radiation is not usually effective.

Although pompholyx is thought by some to be an entity, the majority appear to believe that it is a variety of dermatophytosis or dermatophytid. Often it is but a transient eruption. In any event, ultraviolet ray treatment has proved disappointing.

Alopecia may be divided into alopecia areata and alopecia prematura. The first consists of circumscribed bald patches on the scalp or face. In some instances the entire scalp, the face and even the trunk and extremities may be involved—alopecia totalis. The cause is not known. It may be endocrinologic or neurogenic.

Alopecia prematura may be divided into cases caused by seborrhea capitis (alopecia seborrheica) caused by systemic disturbances such as acute febrile diseases, chronic systemic disorders, neurogenic factors (alopecia systemica) and those cases for which no cause can be found except a family history of early baldness (alopecia idiopathica or hereditaria).

Although ultraviolet radiation has been used extensively by a large number of dermatologists and others in the treatment of all types of alopecia, there is now fairly general agreement that ultraviolet radiation is in no sense a specific, that it is not a hair grower. In amounts insufficient to produce erythema it appears to be useless. Quantities sufficient for vigorous hyperemia probably do no more than hyperemia evoked by any agent—phenol for instance. If this is conceded ultraviolet radiation may be considered to be a useful adjunct for the treatment of alopecia areata and the several types of alopecia prematura. It is not improbable that recovery in many cases of alopecia areata is spontaneous. The prognosis in alopecia idiopathica is unfavorable. If proper attention is given to the constitutional disturbances in cases of alopecia systemica the prognosis is excellent. Early cases of alopecia seborrheica respond favorably to topical applications. Finally, it may be stated that all types of alopecia can be handled as successfully without as with ultraviolet radiation.

Tuberculosis of the Skin and Allied Conditions.—*Lupus Vulgaris*. *Lupus vulgaris* is definitely benefited by treatment with ultraviolet rays. A great deal of time and patience is required but the results often reward the effort. A combination of generalized and localized ultraviolet radiation yields the best results in the treatment of this condition. Excellent results by careful exposure of the entire body to sunlight have been obtained. Concentrated carbon arc light therapy by theinsen method gives the best results as far as concerns regional treat-

ment Beneficial results also may be obtained with the water cooled quartz arc lamp, especially when it is possible to dehematize the area by pressure with the quartz frontpiece on the lamp. Dehematization may be obtained also with local injections of epinephrine, but the results are not as good as with compression. The dose must be heavy—several or many times the erythema dose at each sitting. Of course the reaction is severe, and the treatment is not repeated until the reaction has disappeared.

Such large doses require from five to twenty minutes. Since only a small area (a square inch or two) is covered in one exposure, a great deal of time is required for the treatment of extensive eruptions.

There is enough reliable clinical evidence available to give substantial support to the belief that daily general body irradiation with an air cooled quartz mercury arc lamp is of real value. Solar radiation of the entire body probably gives better results. Such treatments may have to be continued for several or many months. Ultraviolet therapy may be combined with general systemic treatment including bed rest and with such treatment as tuberculin injections, high vitamin well balanced adequate diet and, if proper precautions are taken with roentgen treatment. It is not, of course, possible to cure all cases. A number of complications, such as tuberculous lymphangitis and visceral tuberculosis may prevent the patient from reacting favorably to any treatment.

Lupus Miliaris Dissemminatus As far as is known this type of true cutaneous tuberculosis has not been treated with ultraviolet rays. The eruption is likely to disappear spontaneously in a few months.

Lupus Erythematosus Apparently radiation is not of much value in this condition. At times, discoid patches may be benefited with erythema doses of ultraviolet rays applied directly to the lesions. However, these patches may be made worse by such treatment. General body irradiation was formerly used, but there is sufficient evidence to indicate that erythema is followed at times by the precipitation of disseminate lupus erythematosus. Radiation was used more in former years than at present. General ultraviolet radiation in cases of lupus erythematosus not only yields poor results but may cause dangerous sequelae. Therapy with gold salts and with bismuth has given such satisfactory results that other therapeutic methods are used mostly as adjuvants in selected cases.

Tuberculosis Orificialis Good results may be obtained with ultraviolet irradiation in cases of tuberculosis of the orificial mucous membranes. However, when the desired result is not obtained in a reasonable time, other local methods such as x-rays, grenz rays and the electric cautery or surgical diathermy, should be seriously considered. Most orificial tuberculosis is secondary to involvement of the viscera and general medical attention is required.

Tuberculosis Verrucosa Cutis (wartlike tuberculosis of the skin, verruca necrogenica, anatomic tubercle) Ultraviolet rays have not been found very useful in this disease.

Scrofuloderma Satisfactory results have been obtained in many cases of scrofuloderma with and without tuberculous adenitis. The best treatment appears to be adequate attention to the general health, a suitable diet, tuberculin injections and daily general body irradiation with either solar radiation or artificial ultraviolet radiation. Locally applied ultraviolet radiation alone fails. Stubborn cases in which there is an underlying suppurating tuberculous focus (glands bones) may require surgical intervention.

Erythema Induratum (Bazin's disease) The local application of ultraviolet radiation is of questionable service. These patients should be handled from a general medical standpoint—rest, light exercise diet and general body irradiation (solar or artificial ultraviolet radiation).

Sarcoid Thus far, ultraviolet radiation has not been shown to be of real service in the management of the two types of sarcoid (Boeck type and Darier-Roussy type). Statements made under the headings of Bazin's disease and sarcoid apply also to that apparent variant of these conditions, periphlebitis nodularis necroticans.

Granuloma Annulare Ultraviolet rays appear to be of little if any value in this disease.

Tuberculid Papulonecrotic tuberculids exhibit eruptions which are usually widespread and bilateral and are characterized by remissions and exacerbations. In some cases generalized ultraviolet radiations seem to shorten the course of the disease and in others radiation seems to have no effect. The treatment of lupus pernio with ultraviolet radiation is ineffectual.

Nevi—**Nevus Araneus** Spider nevi can be eradicated with blistering doses of ultraviolet radiation, but electrolysis is a much better method.

Nevus Flammeus Port wine marks are exceedingly difficult to eradicate. Blistering doses of ultraviolet radiation administered by the water cooled quartz mercury arc lamp with compression may occasionally improve very faint nevi of this type and may reduce the color of more pronounced lesions.

Other types of vascular nevi and the pigmented nevi do not respond favorably to ultraviolet ray treatment.

Adenoma Sebaceum Good results with blistering doses of ultraviolet radiation have been obtained in this disorder usually with the water cooled quartz mercury arc lamp with compression.

Telangiectasia This condition, when occurring as a sequel to roentgen or radium treatment, can be improved with ultraviolet radiation. Either the water cooled or air cooled lamp at a distance may produce satisfactory results. As pointed out by Hazen and by C. Guy Lane, x-ray and radium skin has a low toleration for such radiation. Therefore, the initial dose should be small. As a rule, it requires from one to several erythema doses or even blistering doses to destroy the capillaries. It is best not to treat with strong doses of ultraviolet rays most cases of radiodermatitis as too vigorous treatment may in some severe cases cause the tissue to ulcerate. It is difficult to obtain the correct amount of vascular destruction. When the treatment is too vigorous, the treated area is likely to be too white and also the atrophy caused by the x-rays or radium becomes more visible.

Miscellaneous Cutaneous Disorders—**Dermatitis Herpetiformis** and **Pemphigus** There have been numerous reports of good results with general body irradiation with ultraviolet rays in cases of dermatitis herpetiformis and chronic pemphigus. However, others are not convinced that the radiation is of value for the purpose. Evaluation is difficult because these diseases are characterized by exacerbation and remission.

Scleroderma Ultraviolet radiation has been advocated for scleroderma both local applications and general body irradiation being used. The results have been very discouraging.

Milia Ultraviolet rays have been tried in a few cases and have not proved beneficial.

Pityriasis Rosea Ultraviolet radiation has been found useful for shortening the course of pityriasis rosea. One dose, sufficient to cause erythema and exfoliation, may suffice to clear up the eruption. Apparently it is the exfoliation that effects the cure. It is advisable to avoid too severe an erythema, especially for the first dose in severe cases. It is customary to give a suberythema dose at the first sitting to determine toleration. A few days later a full erythema dose may be given. The natural course of this self-limited disease is from one to three months. Subjective symptoms usually are mild or absent and the eruption seldom attacks the face or other exposed parts. For these reasons most patients prefer to avoid the discomfort that is likely to be associated with a widespread sunburn. In some cases of pityriasis rosea the eruption is severe inflammatory and subjective symptoms are annoying and it is doubtful whether ultraviolet radiation is indicated.

Leukoderma The literature contains many reports of good results in the treatment of this disease with local applications of erythema doses of ultraviolet rays with and without general body irradiation. The modern dermatologic consensus is that the method is almost if not completely, useless. As a rule such treatment is likely to make the areas more conspicuous because the white areas do not tan while the surrounding areas become very dark. Recently, occasional satisfactory results have been obtained by painting the white areas with oil of bergamot and applying ultraviolet radiation in quantities sufficient to evoke erythema.

(To be continued)

There is a difference of opinion regarding the efficacy of ultraviolet radiation (general body irradiation) in neurodermatitis. Certainly many patients improve when they are able to indulge in heliotherapy, but it has been impossible thus far to determine whether the improvement is due to a combination of environmental factors (rest, relaxation, contentment, salt water bathing, effect of moving air on the naked skin, change of climate, escape from causative proteins) or to ultraviolet radiation.

Only occasional good results are obtained with artificial ultraviolet radiation, and in these instances improvement might have been due to other factors. Many patients have a low tolerance for radiant heat and appear to be made worse with small doses of ultraviolet radiation. Amounts sufficient for erythema are likely to precipitate an exacerbation.

Eczema seborrheicum (dermatitis seborrheica) presumably a bacterial, rather polymorphous type of eczema in its most simple form may consist of dandruff, a few scaly patches on the face and ears, or excessive oiliness of the face and scalp. The more severe eruptions consist of exudative and crusted patches on the head, scaly patches and patches of follicular papules on the trunk, and erythematous scaly patches under pendulous breasts and in the pubic and crural regions. It is often difficult to differentiate between seborrhea, dermatophytosis and psoriasis. Occasionally ultraviolet radiation appears to give good results, especially erythema doses for chronic dry patches, but in general it may be stated that ultraviolet radiation has not been of much service in the management of this form of eczema.

Eczema hemostaticum (dermatitis hemostatica) generally occurs on the legs of elderly persons and is due primarily to poor local circulation caused by varicose veins, cardiovascular disturbances, renal inefficiency, tight circular garters and so on. Additional causes are scratching and infection with pyogenic organisms. The principal treatment consists in support for the circulation (elastic stockings) and the correction of constitutional disturbances. Ultraviolet radiation appears to be of benefit for the indolent ulcers that so often complicate the disorder and it may be of service when the skin is considerably thickened. On the whole, however, ultraviolet radiation is not efficacious for this type of eczema.

Intertrigo is an erythema occurring in locations where the parts are in contact (axillas, crural region) and is due to irritation, heat and unhygienic conditions. Dermatitis with edema, exudation and crusting, may develop (eczema intertrigo). Differentiation must be made from dermatophytosis. Ultraviolet rays have been used for recurrent eruption with questionable results.

The term infantile eczema signifies no more than eczema occurring in an infant. Usually such eczema is one of the enumerated types or a combination of two types. So far as concerns ultraviolet there are no special indications other than those found throughout the section dealing with eczema.

Many dermatologists claim that ultraviolet rays are useful for many varieties of eczema and in selected cases this is possibly true, but in general terms American dermatologists agree that ultraviolet radiation is not of much value in this disease. It is not indicated in acute eczema. General body irradiation may be of some value in selected cases of chronic eczema. At times, any agent that will evoke hyperemia in a patch of chronic squamous eczema will hasten recovery. Ultraviolet radiation may be used for this purpose, however, judgment is required or the condition is apt to get worse instead of better. Such treatment may be successful but the physician is taking a risk.

Psoriasis, Parapsoriasis, Dermatitis Exfoliativa, Lichen Planus. In psoriasis ultraviolet radiation in amounts sufficient to cause erythema applied to the individual lesions about once a week, will at times promote resolution. Such treatment, however, is not particularly efficacious and if the erythema involves the normal skin, the lesion may spread over the entire area of erythema.

Daily heliotherapy to the entire body, irrespective of the location of the eruption, or daily general body irradiation with artificially produced ultraviolet rays, is thought by many dermatologists to be of value. It is advisable to avoid erythema because the too vigorous treatment of psoriasis, especially the more acute types, may favor the development of dermatitis

exfoliativa. In fact, radiation is contraindicated in the acute types. If general body irradiation is proved to be of real value, it would seem to be a particularly favorable treatment for children. Goeckerman and O'Leary's coal tar technique appears to have given better results in psoriasis than the use of ultraviolet radiation alone. This consists in applying a 3 per cent crude coal tar ointment at night. The next morning the ointment is wiped off. This is followed by irradiation of the entire body, after which a bath may be taken. When possible, the treatment is given daily. The most that can be hoped for in psoriasis is control of the disease, it cannot be cured.

Remissions in parapsoriasis, an incurable disease have been reported with erythema doses of ultraviolet radiation. There are several types of the disease, only two of which have at the present writing responded temporarily to the treatment—the papular and the plaque or patch types.

Ultraviolet radiation has not been found useful in dermatitis exfoliativa.

Pruritus, Prurigo.—Ultraviolet radiation is recommended by some for the various types of essential pruritus—pruritus ani, pruritus vulvae, so called senile pruritus—but the majority of dermatologists have not been favorably impressed with the results. Erythema doses may increase the pruritus.

Ultraviolet rays have been advocated for the relief of pain associated with diseases such as zoster. They appear to be of little service for this purpose.

Prurigo nodularis does not yield well to ultraviolet rays, although a few apparently satisfactory reports have been published. The same statement applies to prurigo mitis and prurigo ferrox.

Diseases of the Appendages.—In hyperhidrosis, ultraviolet radiation is not usually effective.

Although pompholyx is thought by some to be an entity the majority appear to believe that it is a variety of dermatophytosis or dermatophytid. Often it is but a transient eruption. In any event ultraviolet ray treatment has proved disappointing.

Alopecia may be divided into alopecia areata and alopecia prematura. The first consists of circumscribed bald patches on the scalp or face. In some instances the entire scalp, the face and even the trunk and extremities may be involved—alopecia totalis. The cause is not known. It may be endocrinologic or neurogenic.

Alopecia prematura may be divided into cases caused by seborrhea capitis (alopecia seborrheica) caused by systemic disturbances such as acute febrile diseases, chronic systemic disorder, neurogenic factors (alopecia systemica) and those cases for which no cause can be found except a family history of early baldness (alopecia idiopathica or hereditaria).

Although ultraviolet radiation has been used extensively by a large number of dermatologists and others in the treatment of all types of alopecia there is now fairly general agreement that ultraviolet radiation is in no sense a specific and it is not a hair grower. In amounts insufficient to produce erythema it appears to be useless. Quantities sufficient for vigorous hyperemia probably do no more than hyperemia evoked by any agent—phenol, for instance. If this is conceded ultraviolet radiation may be considered to be a useful adjunct for the treatment of alopecia areata and the several types of alopecia prematura. It is not improbable that recovery in many cases of alopecia areata is spontaneous. The prognosis in alopecia idiopathica is unfavorable. If proper attention is given to the constitutional disturbances in cases of alopecia systemica the prognosis is excellent. Early cases of alopecia seborrheica respond favorably to topical applications. Finally, it may be stated that all types of alopecia can be handled as successfully without as with ultraviolet radiation.

Tuberculosis of the Skin and Its Conditions.—Lupus Vulgaris. Lupus vulgaris is definitely benefited by treatment with ultraviolet rays. A great deal of time and patience is required but the results often reward the effort. A combination of generalized and localized ultraviolet radiation yields the best results in the treatment of this condition. Excellent results by careful exposure of the entire body to sunlight have been obtained. Concentrated carbon arc light therapy by the Finzen method gives the best results, as far as concerns regional treat-

ment Beneficial results also may be obtained with the water cooled quartz arc lamp, especially when it is possible to dehematize the area by pressure with the quartz frontpiece on the lamp Dehmatization may be obtained also with local injections of epinephrine, but the results are not as good as with compression The dose must be heavy—several or many times the erythema dose at each sitting Of course the reaction is severe, and the treatment is not repeated until the reaction has disappeared

Such large doses require from five to twenty minutes Since only a small area (a square inch or two) is covered in one exposure, a great deal of time is required for the treatment of extensive eruptions

There is enough reliable clinical evidence available to give substantial support to the belief that daily general body irradiation with an air cooled quartz mercury arc lamp is of real value Solar radiation of the entire body probably gives better results Such treatments may have to be continued for several or many months Ultraviolet therapy may be combined with general systemic treatment including bed rest and with such treatment as tuberculin injections, high vitamin well balanced adequate diet and, if proper precautions are taken, with roentgen treatment It is not, of course, possible to cure all cases A number of complications, such as tuberculous lymphangitis and visceral tuberculosis, may prevent the patient from reacting favorably to any treatment

Lupus Miliaris Dissemminatus As far as is known, this type of true cutaneous tuberculosis has not been treated with ultraviolet rays The eruption is likely to disappear spontaneously in a few months

Lupus Erythematosus Apparently radiation is not of much value in this condition At times, discoid patches may be benefited with erythema doses of ultraviolet rays applied directly to the lesions However, these patches may be made worse by such treatment General body irradiation was formerly used, but there is sufficient evidence to indicate that erythema is followed at times by the precipitation of disseminate lupus erythematosus Radiation was used more in former years than at present General ultraviolet radiation in cases of lupus erythematosus not only yields poor results but may cause dangerous sequelae Therapy with gold salts and with bismuth has given such satisfactory results that other therapeutic methods are used mostly as adjuvants in selected cases

Tuberculosis Orificialis Good results may be obtained with ultraviolet irradiation in cases of tuberculosis of the orificial mucous membranes However, when the desired result is not obtained in a reasonable time, other local methods, such as x-rays, grenz rays and the electric cautery or surgical diathermy, should be seriously considered Most orificial tuberculosis is secondary to involvement of the viscera, and general medical attention is required

Tuberculosis Verrucosa Cutis (wartlike tuberculosis of the skin, verruca necrogenica, anatomic tubercle) Ultraviolet rays have not been found very useful in this disease

Scrofuloderma Satisfactory results have been obtained in many cases of scrofuloderma with and without tuberculous adenitis The best treatment appears to be adequate attention to the general health, a suitable diet, tuberculin injections and daily general body irradiation with either solar radiation or artificial ultraviolet radiation Locally applied ultraviolet radiation alone fails Stubborn cases in which there is an underlying suppurating tuberculous focus (glands, bones) may require surgical intervention

Erythema Induratum (Bazin's disease) The local application of ultraviolet radiation is of questionable service These patients should be handled from a general medical standpoint—rest, light exercise, diet and general body irradiation (solar or artificial ultraviolet radiation)

Sarcoid Thus far, ultraviolet radiation has not been shown to be of real service in the management of the two types of sarcoid (Boeck type and Darier-Roussy type) Statements made under the headings of Bazin's disease and sarcoid apply also to that apparent variant of these conditions, periphlebitis nodularis necroticans

Granuloma Annulare Ultraviolet rays appear to be of little if any value in this disease

Tubercloid Papulonecrotic tuberculids exhibit eruptions which are usually widespread and bilateral and are characterized by remissions and exacerbations In some cases generalized ultraviolet radiations seem to shorten the course of the disease and in others radiation seems to have no effect The treatment of lupus pernio with ultraviolet radiation is ineffectual

Ven—Nevus Araneus Spider nevus can be eradicated with blistering doses of ultraviolet radiation, but electrolysis is a much better method

Nevus Flammeus Port wine marks are exceedingly difficult to eradicate Blistering doses of ultraviolet radiation, administered by the water cooled quartz mercury arc lamp with compression, may occasionally improve very faint nevi of this type and may reduce the color of more pronounced lesions

Other types of vascular nevi and the pigmented nevi do not respond favorably to ultraviolet ray treatment

Adenoma Sebaceum Good results with blistering doses of ultraviolet radiation have been obtained in this disorder usually with the water cooled quartz mercury arc lamp with compression

Telangiectasia This condition when occurring as a sequel to roentgen or radium treatment, can be improved with ultraviolet radiation Either the water cooled or air cooled lamp at a distance may produce satisfactory results As pointed out by Hazen and by C Guy Lane, x-ray and radium skin has a low toleration for such radiation Therefore the initial dose should be small As a rule, it requires from one to several erythema doses or even blistering doses to destroy the capillaries It is best not to treat with strong doses of ultraviolet rays most cases of radiodermatitis as too vigorous treatment may in some severe cases cause the tissue to ulcerate It is difficult to obtain the correct amount of vascular destruction When the treatment is too vigorous the treated area is likely to be too white and also the atrophy caused by the x-rays or radium becomes more visible

Miscellaneous Cutaneous Disorders—Dermatitis Herpetiformis and Pemphigus There have been numerous reports of good results with general body irradiation with ultraviolet rays in cases of dermatitis herpetiformis and chronic pemphigus However others are not convinced that the radiation is of value for the purpose Evaluation is difficult because these diseases are characterized by exacerbation and remission

Scleroderma Ultraviolet radiation has been advocated for scleroderma, both local applications and general body irradiation being used The results have been very discouraging

Milia Ultraviolet rays have been tried in a few cases and have not proved beneficial

Pityriasis Rosea Ultraviolet radiation has been found useful for shortening the course of pityriasis rosea One dose, sufficient to cause erythema and exfoliation, may suffice to clear up the eruption Apparently it is the exfoliation that effects the cure It is advisable to avoid too severe an erythema, especially for the first dose in severe cases It is customary to give a sub-erythema dose at the first sitting to determine toleration A few days later a full erythema dose may be given The natural course of this self-limited disease is from one to three months Subjective symptoms usually are mild or absent and the eruption seldom attacks the face or other exposed parts For these reasons most patients prefer to avoid the discomfort that is likely to be associated with a widespread sunburn In some cases of pityriasis rosea the eruption is severe, inflammatory and subjective symptoms are annoying, and it is doubtful whether ultraviolet radiation is indicated

Leukoderma The literature contains many reports of good results in the treatment of this disease with local applications of erythema doses of ultraviolet rays with and without general body irradiation The modern dermatologic consensus is that the method is almost, if not completely useless As a rule, such treatment is likely to make the areas more conspicuous because the white areas do not tan while the surrounding areas become very dark Recently, occasional satisfactory results have been obtained by painting the white areas with oil of bergamot and applying ultraviolet radiation in quantities sufficient to evoke erythema

535 NORTH DEARBORN STREET - - CHICAGO, ILL.

Cable Address

'Medic Chicago

Subscription price

Eight dollars per annum in advance

Please send in promptly notice of change of address giving both old and new always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY JANUARY 9 1943

ANNUAL DUES NOW PAYABLE

In this issue of THE JOURNAL a colored slip is inserted! Fellows of the A M A and subscribers may use it to remit now. Fellowship dues and subscription are payable in advance. The use of the colored slip at this time will save the Association the expense of postage and clerical effort incurred by sending personal bills to each Fellow and subscriber. The slip, when folded, forms an envelop already addressed and postpaid. Names and subscription prices of all the special journals published by the Association, as well as *Hygeia*, the Health Magazine, are included on the slip. Remittance for any of these other publications may be conveniently included with the amount sent for the annual dues. Those who have already paid will, of course, disregard the colored slip.

PLANNING FOR POSTWAR MEDICAL CARE

Probably few other groups have more interest in the problems concerned in planning for the postwar world than has the medical profession. Many surveys already indicate a general agreement that the provision of optimum health through the widest possible application of the principles of preventive medicine and the treatment of disease and through the best possible distribution of medical services are considered by most of those consulted to be among the first problems to be given consideration. Even satisfactory nutrition for those portions of the world which have already begun starving must in itself depend on medical diagnosis as to the nature of the malnutrition and the means to be followed for nutritional improvement. Few of the suggestions thus far made for constituting suitable

agencies for the study and control of postwar problems have indicated the necessity for dependence on sound medical advice and administration. Such proposals as have come have been the fruit of considerations by economists and statesmen. In Great Britain a medical advisory commission for the minister of health has just been established, it includes the leaders of all the recognized national medical organizations together with Lord Dawson of Penn and Sir Thomas Horder, whose positions in relationship to medical care of the royal family are well known. One wonders why so many years elapsed before the minister of health was given such assistance.

The Beveridge report which has been widely discussed editorially in many newspapers and periodicals in this country, has only recently become available for consideration. Its medical aspects are elucidated in the correspondence from London in this issue of THE JOURNAL. Sir William Beveridge's recommendations are essentially an expansion of Britain's present system of social insurance involving a state paid medical service for all regardless of individual financial status. Medical planning is a function of a special committee of the British Medical Association, the *Lancet* has published a condensation of the report of an independent, anonymous planning group of some two hundred British physicians, separate proposals have also been made in England by the medical communist and other independent agencies. What will come of all these proposals is difficult to conjecture. Presumably all the plans and planning will be tossed into the parliamentary hopper, where any ultimate proposal will have to be subjected to the strainer of the financial considerations. Sir William Beveridge pointed out that his recommendations are concerned 'not with increasing the total wealth of the British people but with distributing whatever wealth is available.' Great Britain is still operating on deficit finance. As was pointed out by the *Pittsburgh Press*, there is little security in red ink. Wealth has to be created before it can be distributed.

In the United States various agencies have been considering the problems of postwar planning. At a meeting of the Committee on War Participation of the American Medical Association (reported elsewhere in this issue) President-Elect James E. Prullin called attention of the committee to the necessity for participation in planning and urged the establishment of some suitable special agencies in the American Medical Association for this purpose. These matters may well come before the House of Delegates at its next session.

A special committee including representatives of the Social Security Board, has made a preliminary report to the President, and another committee appointed by the American Council on Public Affairs, has developed a statement on security as it relates, among other things, to health. These publications have apparently aroused

but little public interest. We in this country are, of course, also concerned with the situation from a financial point of view. As the *Pittsburgh Press* pointed out, the United States government also is operating on deficit finance. "Our public debt has just passed the 100 billion mark.

The social security taxes we have paid into the social security fund have been lent to the government and have been spent."

Various reports emanating from sources in Washington indicate that neither the Senate Committee on Finance nor any of the other agencies which might be concerned with these matters are inclined to expansion of social security legislation at this time. Nevertheless such considerations must come eventually. When they do come, the extent to which the Social Security Act covers the administration of preventive medicine and medical service will be a matter of utmost importance to the medical profession.

Some fundamental concepts should be kept constantly before us. Most important is a realization that conditions in the United States are different from those in any other nation in the world. It would be the height of folly for us to approach this problem with the view that techniques established as suitable in other nations would be equally suitable for us. The American democracy differs, even in its essentials, from the other great democracies. Any technique developed for medical service in this country should be adaptable to the maintenance of the American democracy. The nature and quality of medical service in the United States have always differed from those of other nations. The scale of living of the American people has been of a quality far superior to that generally available elsewhere in the world. Obviously any new techniques that are developed for wider distribution of medical service should not contemplate a considerable depreciation of quality in order to attain wider distribution.

The platform adopted by the American Medical Association urges the principle of local control with financial aid from state and federal sources as needed to accomplish the objectives that are sought. The soundness of this principle as it relates to the functioning of the American democracy cannot be questioned.

Finally comes the principle of free choice. The very basis of the American democracy is free choice. Free choice of the school one attends, the newspaper one reads, the church in which one worships, the store in which one makes one's purchases, the car in which one rides, the bank in which one keeps one's funds, the hospital in which one receives hospital care, the physician and the lawyer whom one consults. Careful reading of the Beveridge plan indicates that such considerations have not seemed particularly to be the concern of those who approach the problems of medical care wholly from a social or economic point of view. Unless

medical care is approached primarily from the medical point of view, the result will inevitably be interference with the progress of medical science and depreciation of the quality of medical service.

SELECTIVE SERVICE DEFERMENT OF PHYSICIANS, MEDICAL STUDENTS AND PREMEDICAL STUDENTS

Under the heading of Medicine and the War in this issue of *THE JOURNAL* appears a bulletin issued by the national headquarters of the Selective Service System to all Selective Service boards. Careful reading will indicate the exact status of physicians, medical students and premedical students at this time in relation to the *Selective Service*.

The Directing Board of the Procurement and Assignment Service, recognizing the necessity for maintaining a continuous supply of qualified young men for training in medicine, has just adopted the following recommendation:

In order to reserve for the study of medicine, dentistry and veterinary medicine certain students of superior ability and already partially prepared in their training who in the normal course of events, would be inducted by Selective Service for general military service before the proposed Collegiate Training Corps is established, the Directing Board of the Procurement and Assignment Service recommends that accredited medical dental and veterinary medical schools give consideration to the early acceptance of qualified premedical, pre-dental and pre-veterinary students for classes to be admitted in the calendar year in 1944, as well as in 1943.

Students so accepted should be clearly qualified and desirable for training in these professional fields. These students if not in an Army or Navy Reserve Corps should be recommended for deferment to their Selective Service boards and these recommendations carried to appeal boards if necessary. Such deferments should be only for the limited period until the proposed Collegiate Training Corps becomes operative. Vacancies in these classes after these advance selections should be filled at a later date.

Students who are accepted for medical schools in accordance with these recommendations will be in a favorable position for deferment by the Selective Service System. It will be observed that premedical students in good standing, who have completed one or more years of premedical work, are recommended by the national headquarters of the Selective Service System for deferment by local boards. Acceptance by a medical school, as suggested, should therefore make it possible to secure deferment for well qualified and particularly desirable premedical students irrespective of their year in college. Indication by the medical schools that certain students are acceptable for admission will provide helpful information to the Army and Navy boards which will be responsible for selecting students to be assigned by them for continuance of premedical training in the proposed Collegiate Training Corps.

Current Comment

PHYSICIANS NEEDED AS REPLACEMENTS IN CIVILIAN SERVICE

Every physician may well take pride in the manner in which the medical profession has responded to the nation's call for service. More than one month ahead of schedule the medical profession voluntarily met the procurement objectives (quotas) of the Army and Navy. The response to calls for service continues, through the Procurement and Assignment Service carefully considered scientific planning of future procurement objectives has been formulated. The willingness of physicians to enlist before quotas were established greatly reduced the number of remaining physicians in some areas. Already three hundred and five older physicians have been voluntarily relocated to new areas as a part of their contribution to the war effort. Opportunities still remain for service in critical areas, boom towns and large industrial organizations in the replacement of those physicians who have gone or who are willing to go into the armed forces. Younger physicians, those under 37 years of age who are physically disqualified for the armed services, are urgently needed. Total war means total effort of every individual for victory. Physically disqualified physicians under 37 years of age may be most effective in the war effort by offering their services to the Procurement and Assignment Service. The state committee of the Procurement and Assignment Service in each state will discuss the arrangements and opportunities for this service with those who volunteer.

MEDICAL SOCIETY HONORS CITIZENS

A novel method for interesting the public in health matters has been developed by the Lake County (Ind.) Medical Society.¹ It has established an award which bears the name of the late Dr. Thomas Oberlin of Hammond, Ind., a charter member of the Lake County Medical Society and for forty-three years a leader in Lake County medical circles. Dr. and Mrs. Oberlin were killed in an automobile accident in March 1941. Four citizens of Lake County were selected by the Lake County Medical Society to receive the Oberlin award. Each of these received a handsome silver plaque in recognition of distinguished service for public health. The four citizens selected for this honor on the first occasion of its award included the editor of the *Gary Post-Tribune* and the editor of the *Hammond Times*. Each newspaper was cited for its "individual and always uncompensated" contributions to the health of the people of Lake County. These contributions, according to the committee on awards, were "impossible to list because the history of these contributions is as long as the history of these great institutions." Another award was given to the president of the Lake County council for his work in combating tuberculosis as president of the Lake County Tuberculosis Association since 1936. A posthumous award to a prominent industrialist was given in recognition of his services as "a dynamic force in the interest of

the health and welfare of the people of this (Lake) county." The establishment of this award recognizes the joint interest of medical and lay groups in public health. The choice of an industrialist, a voluntary health worker and two newspaper editors for the first award is a recognition of the value of community cooperation. Such projects as this and county accreditation, an individual award system established in Minnesota for the control of tuberculosis, typify public health progress in the American spirit with local initiative and community cooperation paving progress.

MEDICAL JOURNALS AND MEDICAL PROGRESS

Evaluation of the periodical literature of medicine is difficult. Casey² has presented an evaluation of the medical periodical literature by means which he believes to be unique and which apparently allow satisfactorily for important variables. The study reported is based on the number of references to British and American periodicals during the first three months of 1934 in the American and British medical literature. First in this list is *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, followed in the second, third and fourth positions by the *Journal of Biological Chemistry*, the *Journal of the American Chemical Society* and the *American Journal of Physiology* respectively. The *Lancet* and the *British Medical Journal* appear in the tenth and eleventh positions. As Casey points out, the hundred journals tabulated were exerting in 1934 the greatest influence on general medical progress, although this influence could have been good, bad or indifferent. Of considerable interest is the evidence that periodicals in the fields of physiology, chemistry and mathematics were then (and are now according to a recent check) playing a large part in current medical progress.

UNSCIENTIFIC SCIENCE SERVICE

In a bulletin issued by Science Service, Washington, D. C., published Dec. 18, 1942 in *Science* magazine, appear the following two paragraphs:

A hint that the shortage of doctors is already affecting the national health picture may be found in the death rate for eighty-eight large cities. For the week ending December 5, the latest on which figures are available this took a big jump, to 135 per 1,000, although there are no signs of epidemics.

With no epidemic and no reports so far of a more virulent type of pneumonia or influenza the only suggested explanation for the increased death rate is lack of medical care resulting from the shortage of physicians.

The inference based on the evidence available discredits the use of even the word science in the service that takes the responsibility for such statements. Observe that figures for one week only are concerned and this without relationship to any evaluation of the usual increased prevalence of respiratory and infectious diseases at this season, the movement of great numbers of people, the changing virulence of disease, and innumerable other factors.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

SELECTIVE SERVICE BULLETIN ON PHYSICIANS, DENTISTS, VETERINARIANS, OSTEOPATHS, STUDENTS AND PREPROFESSIONAL STUDENTS

The following bulletin has been circulated under date of Dec 14, 1942 by the national headquarters of the Selective Service System to all secretaries of service boards

1 Persons Qualified—There are certain persons trained, qualified or skilled in the practice of medicine, dentistry, veterinary medicine and osteopathy who if engaged in the practice of their respective professions, are in a position to perform vital service in activities essential to war production and to the support of the war effort and in activities the maintenance of which is necessary to the health, safety and welfare of the nation

2 Critical Occupations—The War Manpower Commission has certified that in the practice of medicine, dentistry, veterinary medicine and osteopathy, and in training and preparation therefor, there are critical occupations which, for the proper discharge of the duties involved require a high degree of training, qualification or skill. In the accompanying tabulation is a list of 'critical occupations' in medicine, dentistry, veterinary medicine, and osteopathy

3 Consideration of Occupational Classification—The War Manpower Commission has certified that there are serious shortages of persons trained, qualified or skilled to engage in these critical occupations. Accordingly, careful consideration for occupational classification should be given to all persons trained, qualified or skilled in these critical occupations and engaged in activities essential to the health, safety and welfare necessary to war production and essential to the support of the war effort, and persons in training and preparation therefor

4 Students in Preprofessional Training—A registrant who is in training and preparation as a premedical, pre-dental, preveterinary or preosteopathic student, pursuing courses in liberal arts or sciences in a recognized university or college may be considered for occupational deferment after completion of his first academic year in such preprofessional course, and thereafter if he is a full time student in good standing, if he continues to maintain good standing in such course of study and if it is certified by the institution that he is competent and that he gives promise of successful completion of such course of study and acquiring the necessary degree of training, qualification or skill

5 Students in Professional Schools—A registrant who is in training and preparation as a medical, dental, veterinary or osteopathic student in a recognized medical school, dental school, school of veterinary medicine or school of osteopathy shall be considered for occupational classification during the period of such professional course, provided he is a full time student in good standing he continues to maintain good standing in such course of study and if it is certified by the institution that he is competent and that he gives promise of the successful completion of such course of study and acquiring the necessary degree of training, qualification or skill to become a recognized medical doctor, dentist, doctor of veterinary medicine or osteopath

6 Interns—A registrant who has completed his preprofessional and professional training and preparation as a medical doctor, dentist or osteopath, and who is undertaking further studies in a hospital, institution or dental clinic giving a recognized internship, shall be considered for occupational classification so long as he continues the internship but for a period not to exceed one complete year

7 Opportunity to Engage in Profession—When a registrant has completed his training and preparation in a recognized col-

lege or university, or in a recognized hospital, institution or dental clinic, and has acquired the high degree of training, qualification or skill in one of these professional fields, such registrant should then be given the opportunity to become engaged in the practice of his profession in the armed forces or in a civilian activity necessary to the public health, safety or welfare necessary to war production, or essential to the support of the war effort. In many instances following graduation from a recognized college or university, or the completion of an internship, a certain period of time will be required in the placing of such persons in an essential activity. When a registrant has

Critical Occupations Medical, Dental, Veterinary and Osteopathic

Preprofessional student after completion of his first academic year in such preprofessional course

Premedical
Pre-dental
Preveterinary
Preosteopathic

Professional students during full professional course following completion of preprofessional course

Medical
Dental
Veterinary
Osteopathic

Intern in hospital, institution or dental clinic giving recognized internship following completion of professional studies

Medical interns
Dental interns
Osteopathic interns

Persons engaged in practice of their respective professions

Medical doctors
Dentists
Doctors of veterinary medicine (engaged in care of animals raised and maintained for work or food or in the inspection of meat food products)
Osteopaths

been deferred as a necessary man in order to complete his training and preparation, it is only logical that his deferment should continue until he has had an opportunity to put his professional training and skill to use in the best interest of the nation. Accordingly following graduation in any of these professional fields or following an internship, a registrant should be considered for further occupational classification for a period of not to exceed sixty days in order that he may have an opportunity to engage in a critical occupation of his profession in the armed forces, war production, support of the war effort or in an activity essential to civilian health, safety or welfare provided that during such period the registrant is making an honest and diligent effort to become so engaged

8 Deferment Permitted Whether or Not Commission is Pending—The official statement of any recognized premedical, pre-dental, preveterinary or preosteopathic college or university, the official statement of any recognized medical, dental, veterinary or osteopathic college or university, or the official statement of any hospital, institution or dental clinic giving a recognized internship showing that a registrant satisfied the requirements of this bulletin shall be sufficient for the consideration of such registrant for occupational classification on occupational grounds solely. Registrants will be considered for

occupational classification as prescribed in this bulletin without regard for the fact that a commission in the armed forces may be granted to him or is pending

9 Procurement and Assignment Service—In order that every doctor, dentist or veterinarian may render the greatest professional service to the nation the President has created the Procurement and Assignment Service for the purpose of gathering information with respect to the supply of qualified medical doctors, dentists and doctors of veterinary medicine. To work with headquarters of the Procurement and Assignment Service there have been appointed for each state and the District of Columbia a state chairman for medical doctors, a state chairman for dentists and a state chairman for doctors of veterinary medicine. When considering the classification of any registrant who is a

medical doctor, dentist or doctor of veterinary medicine, the director of Selective Service desires that local boards, through the state director, shall consult with the respective state chairman of the Procurement and Assignment Service.

10 List of State Chairmen—Names and addresses of the respective state chairmen of the Procurement and Assignment Service will be provided to state directors from time to time.

11 Effective Period of This Bulletin—This bulletin is effective until July 1, 1943, unless sooner amended. During the effective period of this bulletin the War Manpower Commission is giving further study to the training and preparation and utilization of persons trained in these professional fields.

Lewis B. Hirsch, Director

WAR PARTICIPATION COMMITTEE

A meeting of the War Participation Committee of the American Medical Association was held on Dec. 14, 1942 at the Mayflower Hotel, Washington, D. C. Those present included the following members of the committee: Walter I. Donaldson, chairman, William R. Molony, Sr., Roger T. Lee, John H. O'Shea, Edward R. Cumiffe, Clyde L. Cummer, James E. Paullin, Olin West, Morris Fishbein and Ernest E. Irons. Others present were R. L. Sensenich, Harvey B. Stone, Harold S. Diehl, Thomas A. Hendricks, Frank H. Lahey, Thomas Parran, Warren F. Draper, J. W. Mountain, C. E. Rice, George Baehr, Maxwell E. Lapham, Mary Switzer, Gerald D. Timmons, William N. Hodgkin, George Anderson, Harold Hertford and Russell A. Sands.

Comdr. Max Lapham stated that there were forty or fifty critical areas which were now being studied by the Procurement and Assignment Service for Physicians, Dentists and Veterinarians. Information concerning such areas comes from a wide variety of sources, including governmental agencies, senators, congressmen, the Federal Housing Commission and medical organizations. A number of physicians have been relocated in some critical areas. The Procurement and Assignment Service was able to retain six physicians from going into military service from Mobile, Ala., since there had been too many withdrawn from that area. Attention was called to the importance of study and revision of licensure laws in order to minimize the difficulties of relocation.

Dr. Frank Lahey pointed out that meetings were being planned in the various corps areas of representatives of the Procurement and Assignment Service, the medical profession and the United States Public Health Service to discuss this problem.

Dr. Thomas Parran stated that there was need for additional personnel in the field of public health. At present the need includes 276 physicians, 650 nurses, 450 sanitarians and 250 laboratory technicians. An agreement had been reached between the Procurement and Assignment Service and the United States Public Health Service, and a memorandum had been sent to the district directors of the United States Public Health Service, under the title "Operating Policy on Matters Relating to Shortages of Medical and Allied Personnel, Relationships with Corps Area and State Procurement and Assignment Officials, and Functions of the Division of States Relations, United States Public Health Service, in this field," as follows:

'1 The U. S. Public Health Service and the Procurement and Assignment Service will jointly undertake studies of war industry and extracantonment areas from which shortages of medical and allied professional personnel are reported.

'(a) These studies shall be made jointly by the appropriate corps area chairman of the Procurement and Assignment Service, state medical and dental chairman of the Procurement and Assignment Service and representatives of the U. S. Public Health Service, either the district director or some one detailed by the district director or by the Surgeon General.

'(b) District directors of the U. S. Public Health Service should take the initiative in contacting state and corps area chairmen of the Procurement and Assignment Service in seeking to arrange for such studies. The Procurement and Assignment Service will take the same initiative if information concerning a critical area comes to its attention first.

'(c) When recommendations are being considered for any area it should be kept in mind that the ratio of 1 active physi-

cian to 3000 people is considered by the Procurement and Assignment Service and the U. S. Public Health Service as the minimum compatible with war health standards of the civilian population.

'(d) The findings and proposed recommendations of the survey group should be discussed with a representative group of citizens of the area involved before the report is submitted to Washington.

'(e) Recommendations will not always concern additional physicians or dentists but may deal with the possibilities of spreading the services of physicians already in the community by making available some type of auxiliary services such as hospital facilities, nursing services and medical offices and equipment. In other instances the need may be for the expansion of public health facilities.

'(f) Reports of joint studies shall be submitted to the central office of the Procurement and Assignment Service and to the Surgeon General simultaneously and should be signed by the representatives of the Procurement and Assignment Service and the U. S. Public Health Service making the survey. If representatives making the joint report cannot reconcile differences of opinion regarding the recommendations made, these differences should be indicated in the report. Recommendations should be specific and not general as to the plan for meeting the need, including the number of physicians, dentists, auxiliary personnel and facilities.

2 Many situations where shortages exist can be met through local effort by the relocation of physicians living within the state. It is in areas to which physicians must be transplanted from other states that federal assistance most often will be needed.

3 Licensure for doctors moving interstate will be a difficult problem in some states. However, conferences with the Procurement and Assignment Service and state licensing boards may provide means by which out of state physicians may be granted temporary permits to practice medicine in shortage areas for the duration of the emergency.

4 The general counsel's office in an opinion dated July 28, 1942 states that under the authority of title VI Social Security Act the U. S. Public Health Service may detail its personnel to a state to render medical services "provided the public agency to which these officers are detailed has authority under the law of that state to engage in the activities contemplated therein. This arrangement should be used in areas where other means of giving medical care cannot be arranged."

5 The U. S. Public Health Service usually cooperates with state health departments, therefore the question will arise in considering the detail of personnel to cooperate with and assist the state by rendering medical services in war industry and extracantonment areas whether the state health department has the authority to engage in this type of activity. The general counsel's office is of the opinion that most state statutes fail to indicate either positively or negatively what the state health department's responsibility is with regard to this subject. Hence it may be necessary for the state health officer to make an administrative decision concerning this point.

'6 On recommendation of the state health officer and with the approval of the district director after consultation with the state chairman of the Procurement and Assignment Service, personnel now assigned to state health departments under emergency health and sanitation may be assigned to render medical services in areas where shortage exists. In making such assignments district directors will review the total needs in their respective districts and attempt to meet the most urgent ones.

"7 When doing reconnaissance surveys of war industry and extracantonment areas on your own, district directors will concern themselves as in the past, with shortages in such areas of medical and allied personnel

"8 The Community Medical and Dental Service Section has been established in the States Relations Division to serve

"(a) In a liaison capacity between the U S Public Health Service and the Procurement and Assignment board concerning medical care problems in war industry and extracantonment areas

"(b) In an advisory capacity to district directors concerning local plans for providing and utilizing physicians and allied personnel to render medical care

"(c) As a coordinating office with respect to the various medical care interests of the service, other than those dealing with established beneficiaries

"Senior Surg Carl E Rice is in charge of the Community Medical and Dental Service Section. Asst Surg J M Chisholm and Health Administration Specialist Irma M Ringe are also attached to this section

"9 The Community Medical and Dental Service Section should be kept currently advised concerning plans that are being devised and actions taken to alleviate medical care shortages. Such plans may represent the joint efforts of local medical societies, public health departments, hospitals, visiting nursing associations, councils of social agencies and others

"10 The Budget Bureau will consider making special allocations from the President's Emergency Fund for particular areas of need"

There was discussion as to the safe minimum ratio of physicians to population; it was agreed to give further consideration to the statement referring to a ratio of 1 physician to 3000 population. It was also proposed that a representative of the state medical society be added to the group which would recommend assignment of personnel from state health departments to medical service in areas where shortages exist

Dr Frank Lahey called attention to an action of the Procurement and Assignment Service requesting medical periodicals to publish a call for physicians who would be willing to be relocated for the period of the emergency. Dr Harold Diehl reported a compilation of the status of interns and residents at present in hospitals in relation to military service so that the names of those found physically disqualified could be sent to the state chairmen of the Procurement and Assignment Service as men possibly available for location in depleted areas. It has been estimated that about one third of the entire group of interns and residents are women and men who are physically unfit for service with the armed forces

A discussion followed which was concerned with the extent of the authority of the War Manpower Commission in assigning physicians for various agencies and purposes

Dr John O'Shea presented a statement of the situation in the state of Washington, particularly in the city of Vancouver. In this area which houses the Kaiser shipyards, there were normally 2000 people with 20,000 people in the county and from 90 to 100 doctors. It has been estimated that in July 1943 the city will have 157,000 people with 12,000 new homes. The Kaiser company has 19 physicians in its hospital, Bremerton, which is a navy yard city, had 23 physicians. There were 22,000 people and there are now 90,000 people. In Portland the problem is handled by the Portland Medical Service Bureau. In the plant, which is 16 miles from the city of Portland — men are employed. These are the three major problems in the Northwest

Dr William R Molony described the situation in California stating that the California Physicians Service had been working on the problem in Loma Linda and Wilmington. Some 6000 physicians are associated with the California Physicians Service. Special problems were developed in relation to the housing projects in Marin County and Vallejo

At the Lockheed-Vega plant, which has some — employees and which is employing some — new employees each day (mostly women), all employees are examined beforehand and 12 physicians are required who do nothing except make examinations before employment. The shipbuilding yard did not require such examinations because the unions do not agree to have men examined before employment

Special consideration was given to the problem of the total number of physicians to be supplied to the armed forces by the state of California. Dr John O'Shea pointed out that there had

been competition between the Kaiser and Boeing plants for physicians, salaries rising from \$300 a month to \$450 a month. He also gave the figures as to the number of physicians taken from the various large cities of the state of Washington

LICENSURE OF PHYSICIANS

Special consideration was given to the problem of licensure of physicians and the possibility of temporary licensure for the period of the emergency. A question was raised as to the effect of such temporary licensure on the basic science laws prevailing in many states

Dr Morris Fishbein pointed out that it would be impossible to control movements of physicians wholly by the effects of publicity regarding the need for men in various areas. He thought it desirable that the War Manpower Commission establish as soon as possible the extent of its authority in controlling the movements of members of the medical profession during the period of the emergency. Dr Roger I Lee suggested that there are many social factors involved related to the relocation of a physician at any time and that economic factors also play a large part

Special consideration also was given to the problem of the refugee doctor. One of the purposes of the temporary licensure procedure was to place some of the well qualified refugee physicians in areas where physicians are greatly needed. Dr Edward R. Cunniff stated that there were perhaps 1,000 such refugees available in New York State for transplantation. Dr Fishbein suggested that inquiry be made in the individual states to determine whether or not such refugees would be acceptable for service in areas in which shortages prevail

Dr Fishbein requested that inquiry be made of the War Manpower Commission to state definitely its jurisdiction over members of the medical profession in various circumstances. For instance: What jurisdiction do they have over men in the draft age which includes interns and residents who are physically disqualified? What jurisdiction over alien physicians? What jurisdiction over physicians above draft age who may wish to be relocated and what jurisdiction over physicians in full time salaried positions and industries? It was suggested that the Procurement and Assignment Service undertake to obtain such a statement

A subcommittee which had been appointed to develop a procedure for determining needs of physicians in war industry and extracantonment areas made the following report

The Public Health Service and the Procurement and Assignment Service will jointly undertake studies of war industry and extracantonment areas from which shortages of medical and allied professional personnel are reported

"(a) These studies shall be made jointly by the appropriate Corps Area Chairman of the Procurement and Assignment Service, state medical and dental chairmen of the Procurement and Assignment Service and representatives of the U S Public Health Service, either the district director or some one detailed by the district director or by the Surgeon General

Also the state medical society and the state health department each will be invited to designate a representative to participate in such studies"

PROVISION FOR PREMEDICAL AND MEDICAL STUDENTS

Dr Harold Diehl presented a statement concerning provisions for premedical and medical students and the manner in which classes could be maintained during the period of 1943 and 1944. It was pointed out that official memorandums on these subjects would shortly be issued by the Army and Navy and by the War Manpower Commission and the Selective Service System

AFTERNOON SESSION

At a meeting of the War Participation Committee Dr James Paullin and Dr Ernest E. Irons presented a plan for cooperation of the American Medical Association with the American College of Physicians and the American College of Surgeons in organizing groups of physicians who could be sent to camp hospitals in various portions of the United States to aid in ward rounds, conducting clinics, round tables, lectures and other techniques for instruction and graduate education of the physicians in the armed forces. It was pointed out that the annual sessions of these organizations are not to be held during the duration of the war period and that it would be desirable to develop an agency for the extension of medical information to those men

who are largely out of touch with general medical activities. The College of Physicians had made an appropriation to finance a part of the program, and it was felt that the other organizations concerned could also participate. Dr Olin West stated that the proposal had already come before the Council on Scientific Assembly of the American Medical Association and that a special report was to be prepared for its consideration. Dr Irons explained the methods by which the teams and their participation in the effort would be organized.

Dr Moloney suggested the possibility of utilizing the traveling groups also for extension to civilian physicians. It was proposed that Commander Boitz of the Navy be asked to undertake the organization of this service.

POSTWAR PLANNING

Dr James Paullin called attention to the need of organization of medical services in relationship to postwar planning for medical care throughout the world and the necessity for integrating the efforts of all the various agencies engaged in such problems. Consideration was given to the Beveridge report and to other postwar plans that have been called to the attention of the public.

TEMPORARY LICENSURE

The Committee on War Participation also discussed at some length the necessity for temporary licensure and the proposals of the Federation of State Medical Boards and the Procurement and Assignment Service in this regard.

STATE PARTICIPATION IN PROVISION OF MEDICAL CARE

It was recommended by the War Participation Committee that state medical societies cooperate with the state Procurement and Assignment Service and with the state boards of registration and licensure in determining areas in districts that lack medical service and in plans for providing medical service in such areas when the need arises. The Secretary of the American Medical Association, Dr Olin West, was requested to inform the secretaries of all the state medical associations of the action taken.

STATE COMMITTEES ON WAR PARTICIPATION

It was also recommended that each state medical society develop a state committee on war participation to cooperate in such activities.

ARMY

DR EVARTS GRAHAM INSTRUCTS ARMY OFFICERS IN SURGERY

The Department of Surgery of Washington University School of Medicine, St. Louis, under the direction of Dr. Evarts A. Graham, has arranged for short, intensive postgraduate courses in the specialties of surgery for selected groups of U. S. Army officers. The first group of forty officers arrived November 8 for a six weeks course which will include instructions in a number of the different departments of the medical school. In the first group of student officers were two alumni of Washington University School of Medicine, Lieut. Col. Robert M. Moore '26, and Lieut. Col. Walter Mataska '31.

PROFESSIONAL USE OF NARCOTICS BY MEDICAL OFFICERS

New regulations have recently been issued jointly by the U. S. Commissioner of Narcotics and the Commissioner of Internal Revenue outlining the conditions under which officers of the Medical Corps of the Army and Navy may prescribe narcotic drugs. (7 Federal Register 10770, Dec. 23, 1942). These regulations provide that such officers, in the course of official medical treatment of Army and Navy personnel and members of their families entitled to receive such treatment, will be required to issue prescriptions for these patients which may call for narcotic drugs or preparations. Where the drug or preparation cannot be furnished from official stock, it must be obtained, pursuant to the official prescription, from a drug store duly qualified by registration under the Harrison Narcotic Act to fill narcotic prescriptions. Such prescriptions, issued in the course of official professional practice only, and prepared on official blanks or stationery, such as printed forms of an Army or Navy hospital or dispensary, and otherwise meeting the requirements of narcotic regulations relating to prescriptions, may be filled by a duly registered druggist although they do not bear a registry number of the issuing practitioner. These prescriptions, however, must bear the signature, title, corps and serial or jacket number of the issuing medical officer and must be filed with and retained for the same period as narcotic prescriptions issued by regularly registered practitioners and filled by the druggist.

The foregoing procedure will not apply to prescriptions written by an Army or Navy medical officer in the treatment of a private patient, that is, a patient not entitled to receive medical treatment from the physician in the latter's capacity as a service medical officer. In prescribing and dispensing narcotic drugs to such private patients, the medical officer is subject to all the requirements of the Harrison Narcotic Act, including registration and payment of taxes, as are imposed on other physicians conducting private medical practice.

SYMPOSIUM ON EPIDEMIC KERATO-CONJUNCTIVITIS

A symposium on epidemic keratoconjunctivitis was held at Columbia University College of Physicians and Surgeons, New York, December 4, under the direction of the U. S. Army Surgeon General's Office and in conjunction with the Commission of Neurotropic Virus Diseases and the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army. Dr. John H. Dunnington, director of the Institute of Ophthalmology of the Presbyterian Hospital, New York, spoke on 'History of the Disease from the Hawaiian Outbreak to the Present Time'. Dr. Murray Sanders of the Commission on Neurotropic Virus Diseases, 'The Clinical Picture, Epidemiological Data, Recommendations', Dr. Nelson F. Briley, assistant professor of ophthalmology at the New York Postgraduate Medical School and Hospital, Columbia University, New York, 'Differential Diagnosis', Dr. James E. Perkins, director of the New York State Department of Health, 'Additional Epidemiological Observations (the Schenectady Epidemic)', Dr. John R. Paul, chairman of the Commission on Neurotropic Virus Diseases, 'Role of the Virus Commission in the Problem'. Opening remarks were presented by Col. James S. Simmons and the discussion was opened by Lieut. Col. A. J. Lanza, both of the Surgeon General's Office. Following luncheon clinical cases were presented and various phases of laboratory work used in the diagnosis and treatment of epidemic keratoconjunctivitis were demonstrated.

TO DISCONTINUE OFFICER CANDIDATE SCHOOL AT CARLISLE BARRACKS

With the graduation of the eleventh class from the officer candidate course at the Medical Field Service School, Carlisle Barracks, Pa., on December 23, the work of gradually discontinuing the Officer Candidate School at that post began and will end on March 1. To offset the eventual closing of the medical administrative Officer Candidate School, the number of medical department officers to be trained for field duty beginning New Year's will be steadily increased.

Two hundred and forty-eight enlisted men became second lieutenants in the Medical Administrative Corps at the graduation exercises on December 23 and have already been assigned to administrative duties so that medical officers can be relieved of such duties. The diplomas and commissions were presented by Brig. Gen. Addison D. Davis, commandant of the school, and the oath of office was administered by Lieut. Col. Thomas G. Hester, adjutant of the Army Medical Center, Washington, D. C., himself a senior officer in the Medical Administrative Corps.

BRAZILIAN MEDICAL OBSERVERS

Two medical observers from the Brazilian army recently arrived at the U S Army Medical Field Service School, Carlisle Barracks, Pa., for a few days visit. Lieut Col E Marques Porto and Capt Carlos Puma Goncalves, with the approval of the War Department, were assigned to Carlisle Barracks for seven days. This observation tour follows closely the visit of Gen Joro Afonso de Souza Ferreira, the Brazilian surgeon general, and of Capt Abelardo Lobo, who last year graduated from the Medical Field Service School at Carlisle Barracks. Colonel Porto likewise had visited Carlisle Barracks previously, as he was a delegate to the International Congress of Military Surgery in 1939.

STRENUOUS TRAINING

Without previous army experience a professional group comprising doctors of medicine and dentistry graduated on Dec 12, 1942 following an intensive six weeks course at the Officers Training School at Miami Beach, Fla. About 40 per cent of the academic part of the doctors training consisted in fitting them for work with combat units, including courses in aviation medicine, tropical medicine and field surgery. The doctors and dentists followed a twelve hour day period of training including two strenuous hours of physical training and one hour of drill. Major Sidney Davison, assistant director of training in the medical section, said that most of the new officers had come through the strenuous program in "fine style."

CIVILIAN DEFENSE

NEW COURSES FOR GAS SPECIALISTS

A new five day gas specialist course for persons responsible for the organization of gas defense in the target areas was presented in the six War Department civilian protection schools conducted on behalf of and in collaboration with the U S Office of Civilian Defense. This is the first course to be presented in cooperation with the Chemical Warfare Service for state gas consultants and senior gas officers who are responsible for the organization of community gas defense. Courses have been presented at regional schools for medical school representatives, who have in turn been responsible for the education of practicing physicians in the medical aspects of chemical warfare. These schools have been conducted in the East and plans are under way for the presentation of such schools elsewhere in the United States.

The first session of the gas specialists course was at Amherst College, Amherst, Mass., November 29 through December 4. The course was offered December 13-18 inclusive at the other War Department civilian protection schools at Loyola University, New Orleans, Purdue University, Lafayette Ind. University, Washington, Seattle, Stanford University, Palo Alto, Calif., and Occidental College, Los Angeles.

Presentation of the specialized course dealing with gas defense is part of a new plan of instruction in the War Department civilian protection schools. The ten day general course formerly given by the schools was discontinued with the session of November 1 to November 11. The other courses cover plant protection, basic civilian protection and instruction for staff members.

The gas specialists' course placed emphasis on the administrative organization of state and local gas defense programs and the training of civilian protection personnel and the inter-related activities of all units of the U S Citizens Defense Corps.

at the time of a gas attack. It was an advanced course open to those with college degrees in chemical, sanitary or civil engineering, chemistry or equivalent scientific training.

BLOOD PLASMA FOR CIVILIAN DEFENSE

The Medical Division of the Office of Civilian Defense and the United States Public Health Service reported on Dec 8, 1942 the current status of the blood plasma program which was initiated early last spring.

The report indicates that 130 hospitals have now received grants in aid and are preparing reserves of plasma to total at least 63,130 units. In addition to this reserve 27,500 units of frozen plasma have been obtained through the Army and Navy from blood collected by the American Red Cross. This supply has been distributed. The Medical Division has also procured 37,500 units of dried plasma from blood collected by the American Red Cross and this supply is in process of distribution.

The total reserve, which is largely concentrated in the 300 mile coastal target areas, will be 126,630 units for treatment of casualties resulting from enemy action. In addition, 1,250 units are in Puerto Rico and 250 in Alaska.

In addition to these sources of plasma, the Red Cross is distributing to target areas 5,000 units which will be available to the Office of Civilian Defense for treatment of civilian casualties resulting from enemy action. Many hospitals which have not received grants under the program are also preparing plasma reserves which total approximately 50,000 units.

Plasma required for the treatment of war related injuries may be obtained by any community through its chief of Emergency Medical Service. To meet such emergencies, plasma may be transferred (1) within a state by the state chief of Emergency Medical Service, (2) within a region by the regional medical officer and (3) from one region to another by the Medical Division, U S Office of Civilian Defense.

MISCELLANEOUS

NEW SPONGE RUBBER SUBSTITUTE

A new sponge rubber substitute made of linoleic acid a derivative of vegetable oils, was developed in the Research Laboratories of Bauer and Black (Division of the Kendall Company), Chicago, by Drs H M Strong and Marguerite Hays during the course of investigations with vegetable oil derivatives in cooperation with the Northern Regional Laboratories, U S Department of Agriculture at Peoria, Ill. It is believed that the process does not require anything new in the way of equipment, and plant facilities and the materials involved are at present available. The sponge product can be made in any thickness and in varying densities, and in many respects the properties of the new substitute are so close to those of the rubber that they appear identical. Both the product and the process are being made available to the government for war uses for the duration, and information can be obtained through the Rubber Reserve Section. The company reserves for after the war the commercial rights which may be obtained through patents.

RELIEF WINGS INCORPORATED

This nonprofit organization with headquarters at Airlines Terminal Building (suite 408), 80 East 42d Street, New York City has now available an especially equipped single motored air ambulance for either disaster service or individual emergencies. The organization has enrolled ten flight surgeons and thirty flight nurses for call in New York City for air ambulance relief. Flight nurses and flight surgeons are available also in Boston, New Orleans, Chicago, Albuquerque, N M, Kansas City, Mo and Tampa, Fla. Relief Wings coordinators in eleven sections of the United States have made available to civil air patrol groups sample stretchers which will fit in any one of five large single motored airplanes and medical aid ambulance supply kits are being distributed as the organization's budget permits. Thus there is available in the East at present without specific charges for use of the plane an air ambulance for patients who may need to be removed to hospitals or to other parts of the country. Relief Wings Inc hopes however that donations will be made to the organization, when air ambu-

lance service is needed, which would be commensurate with the actual cost of the flight operation.

The treasurer of Relief Wings, Inc., is Mr. J. Hibberd Taylor, and the chairman of the organization's Aero Medical Research Committee is Dr. Harry V. Spaulding. This organization was started in May 1940 and is now laying plans for a widespread program of humanitarian air service.

Among the sponsors, officers, sectional leaders and advisory committees of Relief Wings, Inc. are nationally known citizens, aviators and scientists. The well known aviatrix Miss Ruth Nichols is the executive director.

TOTAQUINE DOSAGE

According to the *Oil, Paint and Drug Reporter* of Dec. 21, 1942, the Food and Drug Administration believes that manufacturers or distributors of totaquine antimalarial remedies should inform consumers how long the contents of the package will last in the treatment of malaria—whether for the full seven day period or for some shorter period. Proper treatment of malaria with totaquine calls for doses of 30 grains daily for seven days, FDA says.

The administration admits that it is without authority to force such a step but, for reasons of economy in view of the shortages of cinchona alkaloids, considers it a matter that should be given serious consideration by the marketers of the product. For patients to take the remedy only to find that the doses were not sufficiently strong to effect the cure would only be wasting the product. Thus far manufacturers have indicated a willingness to go along on the idea, although some are a little dubious about how it might affect sales in the South where the people have been used to buying quinine in small quantities.

DENTAL EQUIPMENT FOR COAST GUARD STATIONS

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, shipped on Dec. 21, 1942, four cases of portable dental equipment to be used in coast guard stations on the west coast of the United States. The shipment included four foot-operated drills to be used on ship board and in areas without electricity, and dental instruments and material sufficient to set up four complete mobile dental units. The equipment was selected by Lieut. J. T. Reece who, the committee says, is serving with the U. S. Coast Guard.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York, received on December 17 approximately 5000 pounds of surgical instruments rescued from the scrap metal heap, which were donated by Dr. Walter L. Bierring, state health commissioner of Iowa, when it was learned that many of the instruments contributed to the recent Iowa scrap metal campaign were in good condition and would more effectively serve the war effort if reconditioned and made available to the various organizations which call on the committee for help. After the necessary repairs have been made, the instruments will be placed in emergency medical field sets for distribution to the U. S. Coast Guard and to first aid posts, needy hospitals and other recognized relief agencies in the United States and Alaska. The idea of salvaging the instruments for reconditioning came from Harry A. Hurd, DDS, Des Moines, who acted as chairman of the Dental Salvage Committee of the Des Moines District Dental Society in the government's scrap metal campaign. Shortly after the start of the dental drive a campaign for scrap was also directed to physicians under the leadership of Dr. Robert L. Parker, Des Moines, chairman of the Iowa State Medical Society. Contributions were made by 854 persons representing 273 cities and towns in Iowa and 11 other states, including Arkansas, Colorado, Kansas, Montana, Minnesota, Nebraska, New Mexico, Oklahoma, South Dakota, West Virginia and Wyoming. The joint drive was immediately successful, but it was soon apparent that many of the instruments were too good for scrap. In addition to the instruments which will be reconditioned it yielded approximately 1,000 pounds of scrap.

COMMITTEE ON SANITARY ENGINEERING CREATED BY THE NATIONAL RESEARCH COUNCIL

A sanitary engineering committee has been organized, at the request of the Surgeon General of the Army, by the National Research Council through the Division of Medical Sciences acting for the Committee on Medical Research of the Office of Scientific Research and Development. Through liaison officers, advice and assistance on sanitary engineering problems are also furnished to the Navy and the Public Health Service.

As epidemiologic and entomologic advice was deemed necessary, personnel representing these sciences was included. Close liaison with the Surgeon General's Office is maintained through the Sanitary Engineering Branch of the Division of Preventive Medicine. The committee consists of:

Abel Wolman, chairman, professor of sanitary engineering, Johns Hopkins University, Baltimore.
Kenneth D. Mayer, secretary, professor of epidemiology, School of Hygiene and Public Health, 615 North Wolfe Street, Baltimore.
Harold F. Babbitt, professor of sanitary engineering, University of Illinois, Urbana.
F. C. Bishopp, assistant chief, Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, Washington, D. C.
V. M. Filars, chief engineer, Texas State Board of Health, Austin.
Gordon M. Fair, professor of sanitary engineering, Harvard University, Cambridge, Mass.
H. A. Whitaker, chief engineer, division of sanitation, State Department of Health, Minneapolis.

In the several meetings to date the committee has devoted major efforts to the problem of procurement and training of the large number of sanitary engineering personnel required for essential war activities. In addition to the needs for sanitary engineers as commissioned officers in the Sanitary Corps of the Army, the U. S. Public Health Service and the Corps of Engineers, it has considered the utilization of sanitary engineers on a civil service status.

The committee has also considered the sanitary engineering functions performed by the Sanitary Corps of the Army with a view toward providing constructive suggestions on the many problems occasioned by the war, including the safeguarding of army water supplies, the disposal of waste and malaria control.

The program covering future activities of the committee includes a continuation of its present work on the availability of and the demand for sanitary engineering personnel, the orderly procurement of and assignment to military, semimilitary and civilian agencies of trained sanitary engineers, information on military sanitary engineering problems and their solution and a consideration of postwar needs for sanitary engineers and the fields in which they may be most profitably utilized.

The committee has had strong liaison representation from the War Department by the presence in the deliberations of Colonel Simmons, Hardenbergh, Prentiss and Robinson from the Navy by Admiral Stephenson and Commanders Cusling, Tipton and Burton, from the U. S. Public Health Service by Mr. J. K. Hoskins and from the Selective Service in the person of Major Robert A. Bur. The National Research Council representatives in the deliberations have been Dr. Weed, Dr. Dawson and Dr. Forbes and Colonel Larkey.

INFORMATION SERVICE FOR WORKING MOTHERS

A recent release from the Department of Welfare of New York City calls attention to the need for a centrally organized but decentrally operated advice and information service for mothers. The members of the Mayor's Committee on Wartime Care of Children agreed that there is a major need for such a service where mothers who are employed in industry or are about to be employed can secure information as to the facilities which are available for the care of their children. According to the release, as many as six of these local centers may be established as a beginning.

NO MORE BIOLOGIC PRODUCTS IN SYRINGES

The syringe type package for biologic products is one of the latest war casualties. After the present stock of serums, vaccines and antitoxins packaged in single doses with syringes and needles enclosed runs out there will not be any more. According to the *Oil, Paint and Drug Reporter*, the WPB is going to give priority assistance in the future for the syringes and needles.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Lectures on Venereal Disease—Dr Percy S Pelouze assistant professor of urology at the University of Pennsylvania School of Medicine, Philadelphia, and consultant for the gonorrhea control program for the U S Public Health Service, opened a series of lectures in Mobile, January 4. Dr Pelouze will travel throughout the state during the month delivering talks to physicians and nurses and local medical societies.

CONNECTICUT

Personal—The Stamford Medical Society recently gave a dinner in honor of Dr Donald R MacLean, Stamford, who practiced as an anesthetist in Stamford for twenty-five years prior to his retirement about seven years ago.

Society News—Dr Joseph I Linde, health officer of New Haven and formerly president of the state medical society, was recently elected president of the Connecticut Tuberculosis Association. Dr Leroy U Gardner, Saranac Lake N Y addressed the Yale Medical Society recently on "The Action of Silica and Its Neutralization".

Regional Meeting on Mental Deficiency—The annual regional conference of the Northeastern Section of the American Association on Mental Deficiency was held at the Southbury Training School, Southbury, recently. The speakers included Dr Joyce V Deutsch, Southbury on "Encephalography as a Therapeutic Procedure in Convulsive Disorders".

DISTRICT OF COLUMBIA

Study Medical Needs in Washington—The committee on medical services of the Medical Society of the District of Columbia will conduct a survey of wartime medical needs of Washington. The city will be divided into areas. The volume of patients treated by each physician and the number he was unable to attend will be studied by the committee. In a statement to the press, December 20, Dr A Magruder Macdonald, president of the district society, stated that a recent study revealed there is now an adequate supply of physicians in Washington, provided there are not further drastic losses to the armed services and the deficiencies in distribution, now being studied, are remedied.

ILLINOIS

Assistant State Alienists Appointed—Drs Ralph C Hamill, associate professor of psychiatry (Rush) and Irene C Sherman, associate in psychiatry, University of Illinois College of Medicine, Chicago, respectively have been named assistants to the state alienist, Dr Harry R Hoffman to fill a temporary vacancy caused when the former assistants Drs Melvin F O Blaurock, Oak Park, and Samuel H Kraines left for military service on indefinite leaves of absence.

Chicago

Health of Industrial Workers—The Chicago Conference on the Health of Industrial Workers will be held at the Palmer House on January 13 under the auspices of the Chicago Medical Society, Illinois Manufacturers' Association and the division of industrial hygiene of the state department of public health in cooperation with the committee on industrial health of the state medical society, Chicago Board of Health, Chicago Society of Industrial Medicine and Surgery, Chicago Industrial Nurses Club and the Chicago Chapter of the American Industrial Hygiene Association. Among the speakers will be:

Dr Carl M Peterson, Secretary of the Council on Industrial Health, American Medical Association. The Urgent Need for Better Local Industrial Health Organization.
Dr Clarence D Selby, Detroit. Why Do Employees Stay Away from Work and What Can We Do About It?
Dr Milton H Kronenberg. How the Small Plant Can Conduct a Health Program.
Dr Fred H Albee, New York. Problems of Employing the Physically Handicapped.
Mr George P Wardley. The Employer's Viewpoint.
Mr Alfred Borah. The Industrial Commission's Attitude.
Mr Frank R Peregrine. Medicolegal Aspects.

Mr Sterling Morton, president of the Illinois Manufacturers' Association, will act as toastmaster at the dinner meeting and speakers will include Hon Dwight H Green, governor of Illinois on "We Have a Job to Do to Improve the Health of the Industrial Worker, and Dr Walter C Alvarez Rochester, Minn, "The Care and Feeding of Executives".

MARYLAND

Personal—Dr Edward Davens, Baltimore pediatric consultant to the state department of health, has been appointed chief of the bureau of child hygiene to succeed Dr James H M Knox Jr, Baltimore, effective September 1.

New County Hospital—Lanham funds totaling \$635,000 have been made available for the construction of a hospital and nurses' home for Prince Georges County. A 30 acre tract of land has been purchased at Cheverly to accommodate a one story 100 bed hospital and an adjoining 50 bed nurses' home. The new structures are expected to be completed by the end of February. The project was developed by a committee following an action taken about two years ago by the Prince Georges County Medical Society, when it went on record as deeming a hospital necessary and advisable.

MICHIGAN

Bulletin Dedicated to Dr Handy—A recent issue of the Bulletin of the Genesee County Medical Society was dedicated to Dr John W Handy Flint, emeritus member of the Michigan State Medical Society, who has passed his ninetieth birthday. Dr Handy graduated at the University of Michigan Medical School Ann Arbor, in 1884 and has been practicing in Flint since 1885, according to the state medical journal.

Fund to Aid Library—Dr Bert R Hoobler and his wife Icie G Macy Hoobler, Ph D, Detroit, have given \$500 to aid in the development of a Wayne University branch of the Hooker Scientific Library. The fund will be administered by Neil E Gordon, Ph D, chairman of the department of chemistry in the College of Liberal Arts and director of the Hooker Scientific Library, housed at Central College, Fayette Mo.

Secretaries' Conference—The annual County Secretaries' Conference of the Michigan State Medical Society will be held at the Olds Hotel, Lansing, January 24. The tentative program lists the following speakers:

Edward T Broadwell, rationing director OPA, Detroit. The Ration Program as It Affects Physicians.
Capt Harold Mulbar, Michigan State Police, East Lansing. Any Spies in Michigan?
J W Holloway Jr, Director, Bureau of Legal Medicine, American Medical Association, Chicago. Physicians Income Tax for 1942.
Dr L Fernald Foster, Bay City. Facts for the Physician.
Lieut Comdr Maxwell E Lapham, Washington D C. How the Medical Profession Can Meet Military, Industrial Research and Civilian Needs During Warlike.
Earl W Munshaw, LL B, state senator, Grand Rapids. Temporary Licenses and Dislocating of Physicians.
Eric C Nissen, insurance counselor, Detroit. Group Disability Insurance for Physicians.

Cummings Foundation and Detroit Orthopaedic Clinic Merge—Announcement has been received of the recent merger of the Cummings Foundation with the Detroit Orthopaedic Clinic. The foundation was established in 1920 for "the establishment and maintenance of a home for the care, maintenance and education of crippled children. For a time it was in such condition that no assets were available. The original group of trustees was augmented in 1934 by the formation of a foundation which functioned until June 1942. The fund is administered by a board of trustees elected annually by members of the corporation of the Detroit Orthopaedic Clinic. Estimated in 1920 at about \$1,500,000, a large percentage of which was in real estate holdings, the fund has been decreased to about one third of its former value. The Detroit Orthopaedic Clinic, an outgrowth of Sigma Gamma Clinic established in 1920, maintains an outpatient department in the city where approximately 1,000 patients are seen annually, a 50 bed hospital school in the country and a special program for the study of better methods for the care of physically handicapped children. Following the merger the name of Sigma Gamma Hospital School was changed to the George H Cummings Memorial Hospital School according to the terms of the will. Dr Charles W Peabody, Detroit, is chief of staff. Dr Winthrop M Phelps, Baltimore, is acting consultant for the cerebral palsy program, and sixteen surgeons and physicians serve as a consultant board for the agency. The organization offers a total program, with great emphasis on personality adjustment, through all departments. Programs which supplement orthopedic care include child guidance, nursery schools, recreation and vocational placement.

NEBRASKA

Former State Health Director Chosen Congressman-Elect—Dr. Arthur L. Miller, Lincoln, formerly president of the Nebraska State Medical Association and until recently director of the state department of health has been chosen congressman-elect from the Fourth District to the United States Congress.

NEW YORK

Personal—Dr. Simon J. Gormley, deputy commissioner of the Albany Department of Health, has been named editor of the Albany Health Bulletin to succeed Dr. Daniel V. O'Leary who has served in this capacity for many years. In the future the bulletin will be published twice monthly instead of weekly.

—Dr. James P. Kelleher, Poughkeepsie, acting medical inspector in the state department of mental hygiene, has been appointed superintendent of the Rome State School, succeeding the late Dr. Charles Bernstein, Rome.

New York City

William Henry Welch Lectures—Homer W. Smith, Sc.D., professor of physiology and director of the Physiological Laboratories, New York University College of Medicine, delivered a William Henry Welch Lecture at Mount Sinai Hospital of New York, January 5, on 'The Physiology of the Kidney'. A second lecture on the subject will be given, January 12.

Insurance Superintendent Chosen President of Hospital Service—Louis H. Pink, LL.D., New York State Superintendent of Insurance since 1935, has been elected president of Associated Hospital Service of New York, filling the vacancy that occurred with the death of Dr. Sigismund S. Goldwater. Mr. Pink was to leave his office as superintendent of insurance on December 31.

New Head of Tonometer Station—The National Society for the Prevention of Blindness has announced that Dr. Mark J. Schoenberg, chairman of its glaucoma committee is now in charge of the station for checking the accuracy of original Schiotz tonometers which is maintained at the headquarters of the society, 1790 Broadway. Dr. Adolph Posner, who formerly directed the tonometer checking station, is on active duty with the United States Army Medical Corps.

Welfare Commissioner Granted Leave of Absence—William Hodson, LL.B., who has just completed his ninth year of service as commissioner of public welfare of New York City, has been granted a two months leave of absence by Mayor LaGuardia so that he may undertake a mission for Herbert H. Lehman, LL.D., former governor of New York and now director of Foreign Relief and Rehabilitation. Commissioner Hodson's leave will begin about January 15.

Dr. Magelaner Appointed Superintendent of Kings County Hospital—Dr. Israel Magelaner, formerly medical superintendent of Harlem Hospital has been appointed medical superintendent of Kings County Hospital, Brooklyn. He succeeds Dr. Emanuel Giddings who left to join the army medical corps. Dr. Emanuel W. Lipschutz, who has been acting medical superintendent at the Kings County Hospital, has been named medical superintendent of the Harlem Hospital, succeeding Dr. Magelaner.

NORTH CAROLINA

Duke University Withdraws Aid from Maternity Clinic—Effective March 24 sponsorship of the maternity clinic of the Charlotte department of health will be discontinued by the Duke University School of Medicine, Durham newspapers report. Similarly, after that date, supplies for the clinic are not to be furnished by the school nor is Duke to continue to pay \$30 a month to apply on the salary of a nurse employed in the clinic. There is hope that a plan may be worked out whereby aid might be obtained from the state board of health to assure uninterrupted conduct and maintenance of the clinic.

OREGON

Members of State Board—Dr. Edward H. McLean, Oregon City, was recently appointed by the governor a member pro tem of the state board of medical examiners to succeed Dr. Frank E. Fowler, Astoria, who is serving in the U. S. Army. Dr. Harold L. Blosser, Portland, is president of the board, and Dr. Linford S. Besson, Portland, is secretary-treasurer. Other members of the board are Drs. Carl G. Patterson, Baker, Charles C. Newcastle, Portland, Irvin R. Fox, Eugene, and J. L. Ingle, D.O., La Grande.

PENNSYLVANIA

Supervision of Typhoid Carriers Requested—The 1943 session of the Pennsylvania legislature will be asked to place all chronic typhoid carriers under state supervision, in accordance with a resolution advanced by the Lancaster City and County Medical Society and adopted recently by the state medical society. If the action is taken, the carriers would be registered and supervised but would be given limited pay to supplement their earned incomes for losses in salaries or wages resulting from restricted employment.

Programs on Industrial Hygiene—County medical societies throughout the state are urged to present during February a program on industrial hygiene which has been endorsed by the state medical society. In order that there may be complete uniformity of presentation the commission on industrial health and hygiene of the society will furnish texts of papers to be presented. The subjects will cover objectives of organized medicine in industrial health and hygiene, medical and non-medical problems in the field and methods necessary to attain described objectives. The commission urges the societies to present this material, no matter what other commitments are planned.

Philadelphia

Roentgen Survey at Navy Yard—The Philadelphia Tuberculosis and Health Association is conducting an x-ray survey of civilian employees at the Navy Yard in Philadelphia. Between 50,000 and 60,000 persons will be given examinations. The work is being done as a joint project of the tuberculosis association and the division of tuberculosis of the state department of health with the cooperation of officials at the Navy Yard and the U. S. Public Health Service. The Bulletin of the Pennsylvania Tuberculosis Society states that the survey is the most extensive case finding effort that has been undertaken in Philadelphia.

Hospitals Require Patients to Be Vaccinated—Virtually all of the hospitals in the city are requiring vaccination of all patients and personnel to keep a smallpox outbreak in the city from entering the city proper, newspapers reported. More than 3,000 persons have been vaccinated within two weeks at the Philadelphia General Hospital and the municipal hospital for contagious diseases. Thousands in other hospitals and state institutions have been ordered vaccinated, it was stated. The orders were disclosed after the Abington Memorial Hospital at nearby Abington was quarantined under police guard on December 31 following the admittance of a 44-year-old patient with smallpox. Eastern Pennsylvania has reported 37 cases in the first outbreak since the last one it was reported. THE JOURNAL, January 2, page 61 reported an outbreak of smallpox in an Amish section in Kishacoquillas Valley.

TEXAS

Changes in Faculty at Texas—Included among the recent changes in faculty at the University of Texas Medical Branch at Galveston are the appointments of Charles B. Allen, Ph.D., as assistant professor of anesthesiology and Dr. Edward J. Lefebvre as assistant professor of internal medicine. Dr. George M. DeChard, Jr. has been named associate professor and clinical biochemist at the John Sealy Hospital.

Hospital Memorial to Physician—The Newton Memorial Hospital was recently opened in Cameron. Chartered as a nonprofit organization, the hospital was founded to commemorate the life and work of the late Dr. William R. Newton, Sr., who at the time of his death in 1938 was a state senator. The hospital was built from the home of the late Dr. Newton by expanding certain parts of the building according to the state medical journal.

VIRGINIA

University News—The Medical College of Virginia Richmond, has received a grant of \$8,400 from the Office of Scientific Production and Research of the U. S. government for the continuation of research on shock, which is being done by Dr. Everett I. Evans, assistant professor of surgery. Dr. Tinsley R. Harrison, professor of medicine, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C. delivered the Alpha Omega Alpha Lecture at the medical college, November 24 on 'Cardiac Dyspnea'. The lecture is sponsored annually by the Alpha Omega Alpha fraternity.—The Nutrition Foundation has given a grant of \$3,000 to Alfred Chanutin, Ph.D. for continuation of his investigation of "fat metabolism in the 'nephritic' rat" at the University of Virginia, Charlottesville.

GENERAL

New Trustees of Pathology Board—Dr Paul R Cannon, professor of pathology, University of Chicago School of Medicine, and Dr Robert A Moore professor of pathology Washington University School of Medicine, St Louis, were recently elected trustees at large of the American Board of Pathology.

Internal Medicine Board Reduces Fee—The American Board of Internal Medicine announces a reduction in its registration and examination fee from \$40 to \$30. The certificate fee will remain at \$10, making a total of \$40. The oral examination fee in the subspecialties will remain at \$10. The reduction in fees became effective on January 1 and will apply to candidates for the written examination on February 15 whose applications have not been accepted for a previous examination.

Van Meter Prize Awarded to Rochester Physicians—The American Association for the Study of Goiter recently announced that the Van Meter Prize has been awarded to Walter Mann BS, research fellow in radiology, and Charles P Leblond, University of Rochester School of Medicine and Dentistry, Rochester, N Y, for their essay on "Chemical Transformation of the Iodine Fixed by the Thyroid Gland." Honorable mention was given to Dr John Douglas Robertson London, for his essay on "The Nature of the Disordered Calcium and Phosphorus Metabolism in Thyrotoxicosis and Myxedema" and Major Monroe A McIver, M C, A U S and Mrs Eleanor A Winter, Cooperstown, for their work on "Liver Changes Occurring in Hyperthyroidism with Special Reference to the Deleterious Effects of Anoxia."

Resurvey of Graduate Nurses—On January 1 a nationwide survey of graduate registered nurses was undertaken by the U S Public Health Service at the request of the subcommittee on nursing of the Office of Defense Health and Welfare Services. A questionnaire is being sent to nurses. Return postcards have been provided by the public health service and will be distributed in the states by the state agent appointed by the service for the purpose. Local nursing councils for war service and district nursing associations will cooperate in locating graduate nurses in their communities. The completed questionnaires will be retained in the local areas, tabulations of data being sent to the state agents, who in turn will send a complete tabulation for the state as a whole to the public health service in Washington, D C. It is considered essential that every graduate nurse, married or single, active or inactive, fill out a questionnaire and return it to her state agent at once. Nurses who have not received the card may secure one from the state nursing council for war service or the state nurse's association.

Request for Contacts with Persons Interested in Medical Aspects of Crime—The Medical Correctional Association, an affiliate of the American Prison Association, is interested in establishing contact with all professional personnel who are especially concerned with or interested in the medical aspects of crime. Dr John D Reichard U S Public Health Service Hospital, Lexington, Ky, is president of the association, and other officers are Drs John W Cronin El Reno, Okla., and Lawrence Kolb Washington, D C vice presidents, and Dr Robert M Lindner, Lewisburg Pa, secretary-treasurer. Membership in the association is confined to the following groups:

Physicians employed in penal and correctional institutions or jails
Physicians social welfare workers and special workers engaged in medical research work in penal and correctional institutions or jails
Physicians psychologists social workers and special workers engaged in medical research work in connection with institutions or hospitals for the mentally ill mentally defective individuals juvenile delinquents defective delinquents outpatient or behavior clinics dealing with any aspect of crime or its prevention criminal juvenile and domestic relations courts parole probation public and private schools colleges and universities and federal state county and municipal public health organizations
Any person who though not automatically falling in any one of the three aforementioned groups presents satisfactory evidence of being engaged in research or an occupation in which the medical aspects of crime are acknowledged as important features.

Joint Orthopedic Meeting—The eleventh annual meeting of the American Academy of Orthopaedic Surgeons and the thirtieth annual session of the Clinical Orthopaedic Society will be held at the Palmer House Chicago January 17-20. On Sunday there will be a panel discussion on 'Chemotherapy in War Wounds' with Drs Frank L Meleney New York John S Lockwood Philadelphia, Champ Lyons Boston and Alton Ochsner New Orleans, as the speakers. Monday morning Chicago members of the Clinical Orthopaedic Society will present a clinical program and in the evening there will be a debate on the Kenny method of nursing care in poliomyelitis. Foreign guests on the academy program will be Dr Herman de las Casas, Caracas, Venezuela, and Brigadier Walter Rowley Bristow, formerly of London now chief orthopedic surgeon

of the Royal Army Medical Corps. One session will be devoted to "Complicating Trauma Associated with Orthopedic Casualties." There will be instructional courses and scientific motion pictures every morning and afternoon. Included among other speakers on the academy program are:

Dr Arthur B LeMesurier Toronto Canada Importance of Leaving a Good Amputation Stump
Dr Fred H Albee New York Treatment of Nonunions of Gunshot Fractures With and Without Loss of Substance
Dr Robert I Harris Toronto Fractures of the Os Calcis Principles of Treatment with Improved Technique and the Results Obtained by It
Dr John Alexander Ann Arbor Mich Injuries of the Chest
Dr Dallas B Phemister Chicago Local Excision and Massive Transplantation in a Selected Series of Sarcomas Involving the Long Bones
Dr J Warren White Greenville S C Total Carpectomy for Intractable Wrist Flexion
Dr Francis J Halford Honolulu Hawaii A Civilian Surgeon's Evaluation of Achievements and Mistakes

Meetings of Ear, Nose and Throat Society—The Eastern Section meeting of the American Laryngological Rhinological and Otolological Society will be held in Hartford Conn January 15. Speakers will include:

Drs Gordon D Hoople and Irl H Blaisdell Syracuse N Y The Problem of Acute Serous Otitis Media
Dr Raymond H Marcotte Hanover N H Local Sulfanilamide Therapy in Acute Mastoiditis
Dr Julius W McCall Cleveland Preliminary Voice Training for Laryngectomy

The Middle Section meeting will be held in Detroit January 20. Among the speakers will be:

Scott N Reger Ph D Iowa City Correlations Between Air and Bone Conduction Acuity Over Wide Frequency Ranges
Dr George J Thomas Pittsburgh Pentothal in Ear Nose and Throat Surgery

Dr Elisha S Gurdjian Detroit Treatment of Skull Fractures in Relation to Nasal Sinuses and the Temporal Bone

At the Southern Section meeting in Chattanooga, Tenn January 28 the speakers will include:

Dr J Hallock Moore Huntington W Va Meniere Syndrome
Dr Lester A Brown Atlanta Ga Osteomyelitis of the Frontal Bone
Drs Lee Cohen and Samuel L Fox Baltimore Atresia of the External Auditory Canal

The meeting of the Western Section in Portland, Ore January 31, will be addressed, among others by:

Olof Larsell Ph D Portland The Auditory Apparatus and the Inception of Hearing
Dr Ralph A Fenton Portland Local Use of the Sulfonamides
Dr Albert B Murphy Everett Wash A Neuropharyngeal Syndrome Suggesting Virus Origin

LATIN AMERICA

Personal—The government of Cuba appointed Dr Juan Miguel Portuondo Domenech, Havana, minister of public health and social aid. Dr Miguel Etchebarne, Santiago was recently appointed to a similar position in Chile by the government of Chile.

Hospital Service Praised by Chilean Federation—The Medical Federation of Chile devoted the July-December 1942 issue of *Medicina Social* in its entirety to an extensive outline of hospital service in the United States. This issue is dedicated to the forty-fourth annual convention of the American Hospital Association held in St Louis this past October. Thirty pages comprise a narrative, statistical and graphic presentation of hospital service in the United States. The cover page is illustrated with the American flag, a picture of the New York Hospital and an inscription tendering it as a homage for the forty-fourth annual convention of the hospital association. It also contains a forethought on the future of medical science which reads "We have before us a new frontier governed by technical, economic and social forces in contrast to our present concept of medicine. Let's be prepared." The editorial material in Spanish, written by Dr Gustavo C Fricke director of the Hospital de Vina del Mar Valparaiso Chile contains an article on the history of the first hospital in the United States and the evolution of hospital service to our present times, the distribution of hospitals in the United States, their classification giving special emphasis to the hospital organization in the New York metropolitan area, the cost of medical care, medical staff organization in the hospitals of the United States, the role of physicians and nurses in the hospital field and the education of technical personnel.

CORRECTION

Public Health in Chile—In the Buenos Aires letter in THE JOURNAL, Oct 17 1942 page 549, in the ninth line from the bottom of the first item entitled "Public Health in Chile" the number 3600 should have been 3,600,000.

Foreign Letters

LONDON LETTER

(From Our Regular Correspondent)

Dec 4, 1942

Medical Committee to Advise Minister of Health

As previous letters to *THE JOURNAL* show, the war will bring about great changes in this country, and among these the practice of medicine must be included. Already several medical committees have investigated the subject. It is now stated in the House of Commons by the Ministry of Health that the government has set up a Medical Advisory Committee to advise the minister of health on the medical aspects of problems affecting the health of the people. The minister has for some time felt the need for associating with his work a representative body of medical men and women engaged mainly in the clinical practice of their profession. The members of the committee include the presidents of the Royal Colleges of Physicians, Surgeons and Obstetricians and Gynecologists, the chairman of the council of the British Medical Association, Prof. Henry Cohen, Prof. Harry Platt, Lord Dawson of Penn and Lord Horder.

Recruiting for Army from Medical Staffs of Hospitals

The universal recruiting of all classes for the fighting services has given rise to difficulties in the case of persons engaged in work necessary for the community. A prominent example is the medical profession and particularly the staffs of hospitals. Under present conditions it has been found impracticable to arrange for traveling army medical boards to visit hospitals for the purpose of examining the male medical staffs who are of military age, as was hoped. The only alternative was to use fixed centers, necessarily limited in number. This has entailed undue inconvenience and loss of professional time. It has therefore been decided to make the examinations at selected hospitals in the emergency hospital scheme by senior members of the staff of the hospitals. But as the decision as to medical fitness or otherwise of a physician for service must rest with the War Office, this examination by a civilian practitioner can not finally determine the matter. If he finds that the physician is not physically fit for general service the army council will arrange for his examination. But a physician found fit at the civilian examination will not be further examined unless and until he is nominated for a commission. Notwithstanding the provisional nature of the civilian examination, it will serve the purpose for which the arrangements were initiated by facilitating the task of the hospital authorities in planning ahead their staffing.

Social Reform to Produce Freedom from Want The State to Provide Medical Treatment for All

On June 10, 1941 a minister announced in the House of Commons that he had arranged for a comprehensive survey of the existing system of social insurance and allied services which would be considered in due course by the Ministerial Committee on Reconstruction Problems, and that well known economist Sir William Beveridge had accepted the invitation to become chairman of an interdepartmental committee which would conduct the survey. The committee was composed of government officials from the various departments involved. Later it was recognized that it would be difficult for these officials to commit themselves on issues of high policy involving their own departments. It was decided that Beveridge alone should be responsible for the report, while the officials acted as his advisers and assessors on the various technical and administrative matters with which they are severally concerned.

Beveridge's report has now been published. It commits the government, which has to examine it, to nothing, but there can be no doubt that something on the lines of the report is bound to be done. The discussions on social reform brought about by the profound dislocation of our normal activities necessitated by the war portend great changes. Our natural conservatism is due to an instinct to preserve what has been tried and to distrust of what has not been tried. Provision for most of the many varieties of need due to interruption of earnings and other causes that may arise in modern industrial communities has already been made on a scale not surpassed and hardly rivaled in any other country. In only one respect—limitation of medical service both in its range of treatment and in the classes for whom it is provided—do we fall short of what has been done elsewhere. For one thing we fall short in providing cash benefit for maternity and funerals and in the system of workmen's compensation.

Our social insurance and the allied services are conducted by a complex of disconnected administrative organs, proceeding on different principles, doing invaluable service but at an unnecessary cost. Limitation of compulsory insurance to persons under contract of service and below a certain remuneration if engaged in nonmanual work is a serious gap. Many persons working on their own account are poorer and more in need of state insurance than employees. There is no real difference between the needs of sick and the needs of unemployed persons, but they get different rates of benefit, involving different conditions. There are three different tests for non-contributory pensions, for supplementary pensions and for public assistance.

Beveridge lays down three guiding principles. 1. Any proposals while using to the full the experience of the past, should not be restricted by considerations of sectional interests established in gaining that experience. A revolutionary moment in the world's history is a time for revolutions, not for patching. 2. Organization of social insurance should be treated as only one part of a comprehensive social progress. Fully developed it may provide income security, it is an attack on want. But want is only one of five obstacles on the road of reconstruction. The others are disease, ignorance, squalor and idleness. 3. Social security must be achieved by cooperation between the state and the individual. The state should offer security for service and contribution but should not stifle initiative, opportunity or responsibility. It should encourage each individual to provide more than a minimum for himself and his family.

The scheme covers all citizens without upper income limits but has regard to their different ways of life and is classified in its application. Six main classes are recognized: (1) employees, (2) others gainfully employed, including employers and independent workers, (3) housewives that is, married women of working age, (4) others of working age not gainfully occupied, (5) those below working age and (6) those retired and above working age. The sixth class will receive retirement pensions and the fifth will be covered by children's allowances. The four other classes will be insured for security appropriate to their services. All classes will be covered for comprehensive medical treatment, rehabilitation and funeral expenses. Every one in classes 1, 2 and 4 will pay a single security contribution by a stamp or single insurance document each week or combination of weeks. In class 1 the employer will also contribute. The contributions will differ from one class to another according to the benefits provided and will be higher for men than for women. As a substitute for unemployment benefit, training benefit will be available to assist persons to find new livelihoods if their present ones fail.

Unemployment benefit, disability benefit, retirement pension and training benefit will be at the same rate irrespective of

earnings. This rate will provide by itself the income necessary for all normal classes. There will be a joint rate for a man and wife who are not gainfully occupied. When there is no wife or she is gainfully occupied there will be a lower single rate. Unemployment benefit will be subject to attendance at a work or training center after a certain period. Pensions other than industrial will be paid only on retirement from work. They may be claimed after the minimum age, 65 for men and 60 for women. If retirement is postponed, the rate will be paid above the basic.

Medical treatment covering all requirements will be provided for all citizens by a national health service organized under the health departments. Postmedical rehabilitation treatment will be provided for all persons capable of profiting by it. There will be a comprehensive national health service for the prevention and cure of disease and a rehabilitation service fitting for employment by both medical and postmedical treatment. The health service will insure that for every citizen there will be available whatever treatment he requires in whatever form he requires it. The medical part of the scheme may be described as an extension, with much improvement, of the present panel system from manual workers and persons with small incomes to every one and to every form of treatment. What will remain of private practice? The answer "Very little if any" can be safely given. The reaction of the medical profession to the scheme cannot yet be stated. It has been favorably received by all the political parties. Of the advantage of unifying all health services, with their inconsistencies and unnecessarily high costs of administration, there can be no dispute. What will probably give rise to controversy is extending social insurance to all, including millionaires. But the colossal taxation of high incomes, likely to last for years after the war, may diminish very much the number of rich. This taxation extends as high as thirty-nine fortieths of big incomes, and therefore the state provided medical service may be useful even to millionaires.

Compulsory Treatment of Venereal Disease

In contrast with the compulsory treatment of venereal disease in other countries, the arrangements in this country have been based exclusively on voluntary attendance. This is in accordance with that respect for the freedom of the individual which is characteristically British. But here the obvious criticism is that what is granted is freedom to spread disease. The voluntary system has had a large measure of success, and before the war the incidence of venereal disease was low and compared favorably with that of other countries. The war has now accustomed us to limitation of our freedom in many directions, and for good reason a new defense regulation introduces compulsion for the treatment of venereal disease in certain carefully defined circumstances. The new regulation leaves the voluntary basis unchanged but provides for compulsion where necessary to bring under treatment a group of persons—small in numbers but responsible for much harm—who are impervious to methods of education and persuasion and refuse to attend for treatment although known to be infected and to be spreading infection.

The regulation provides that persons named by two separate patients under treatment as the suspected source of their infection can be required, by notice served on them by the health officer of the district in which they live, to attend for examination and, if necessary, for treatment by a "special practitioner," and to continue treatment in accordance with his directions until they are certified as free from venereal disease in a communicable form. A special practitioner is defined as one employed or qualified to sit as a venereal disease officer of a treatment center, a specialist in venereal diseases in the

fighting services or any other practitioner designated for the purpose by the minister of health.

The regulation imposes on "special practitioners," on receiving information from a patient under treatment for venereal disease as to the person from whom he suspects that the disease was contracted ("the contact"), the duty of sending to the local health officer particulars of "the contact." All information is to be treated as strictly confidential. A special practitioner is to serve on the contact (if found on examination to be suffering from venereal disease) a notice requiring attendance for treatment. A special practitioner in private practice is under no obligation to treat a contact as a private patient but, if he does, he must discharge the duties laid down in the regulation. If a patient fails to comply with a notice requiring him to attend for treatment or to follow directions given him, he becomes liable to a maximum penalty of three months' imprisonment or a fine of \$500 or both. There are also penalties for giving false information in an attempt to blackmail some other person.

Tuberculosis Among Young People

The first Varrier-Jones lecture was delivered by Wing-Commander R. R. Trail, an expert on tuberculosis. His subject was "The Early Diagnosis of Pulmonary Tuberculosis." He said that except in a disappointingly small percentage of cases we were a long way from the early diagnosis of pulmonary tuberculosis. Tuberculosis now claimed half the total deaths from all causes at ages between 15 and 24. In the air force 40,119 members, including women of the auxiliary service, had been examined by mass roentgenography. Miniature roentgenograms, which can be made at far lower cost and at seven times the speed of full size ones, were taken. Despite the fact that 30,130 men concerned had within the previous six months a stricter medical examination than before, with a view to selection for special duties, the results of roentgenography of these unusually "fit" subjects showed that 65, 22 per thousand, exhibited signs of active disease, and 108, 36 per thousand, signs of inactive disease.

For the 9,989 women roentgenographed the figures were even worse. 38, 38 per thousand, had active disease, and 56, 56 per thousand, had inactive. The highest figures per thousand occurred in the age groups up to 29, being much greater in women than in men. While the incidence of active disease was practically 1 per thousand more for women in the age group 20-24, for women under 20 it was double that of men. For inactive disease the incidence in women under 20 was four times as great as among men, and in the age group 20-24 one and a half times as great.

The figures show that among our supposedly healthy adolescent and young adult population between 18 and 24 some 3 per thousand had unsuspected active tuberculosis and that more than 1 in 2,000 was a potential source of infection, as, unknown to himself, the patient had positive sputum. We have a population of some 5 millions in these age groups. This means that some 15,000 persons in Britain have unsuspected tuberculosis. All of them require at least expert supervision and advice, and many are in need of treatment. These figures relate to persons without admitted symptoms. The conclusion is that some 25 per cent more cases can be found in the early stage of tuberculosis by mass roentgenography than by the ordinary methods of diagnosis.

Royal College of Surgeons a Meeting Place for American and Canadian Medical Officers

The council of the Royal College of Surgeons has decided to offer the use of the library as a meeting place for American and Canadian medical officers.

Deaths

Joseph Rilus Eastman * Indianapolis, Central College of Physicians and Surgeons, Indianapolis, 1894, Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1897, professor emeritus of surgery at the Indiana University School of Medicine, president of the Indiana State Medical Association in 1919 and of the Indianapolis Medical Society in 1925, member of the American Surgical Association and of the Societe Internationale de Chirurgie, member and in 1913 1914 president of the Western Surgical Association, a founder, fellow and formerly governor of the American College of Surgeons, received a certificate of merit for an exhibit of fetal peritoneal folds by means of special photographs and drawings in the Scientific Exhibit of the American Medical Association in 1913 and was a member of the House of Delegates of the Association from 1912 to 1915, in 1917, from 1919 to 1922 and in 1924, during World War I was a director of the American Hospital in Vienna, Austria, and received the Austrian Imperial decoration of the Red Cross for his work there, later served as a major in the medical corps of the U S Army and as a member of the general medical board of the Council of National Defense, formerly on the staffs of St Vincent's and Deaconess hospitals, owner and director of the Joseph Eastman Hospital, visiting surgeon at the Indianapolis City Hospital, aged 71, died, November 29, of diabetes mellitus

Howard Bennett Mettel * St Louis, University of Michigan Medical School, Ann Arbor, 1921, since Oct 1, 1942 director of medical and health service of the Midwestern Area of the American Red Cross, served as assistant professor of pediatrics and assistant in medical economics and postgraduate instruction at the Indiana University School of Medicine, Indianapolis, instructor of pediatrics at his alma mater from 1923 to 1925, member of the Indiana State Medical Association, specialist certified by the American Board of Pediatrics, Inc member of the American Academy of Pediatrics, for many years chief of the bureau of maternal and child health of the Indiana State Board of Health and acting director of the division of services for crippled children in the state department of public welfare at Indianapolis, in 1940 was elected secretary, in 1941 vice chairman and later chairman of the maternal and child health division of the American Public Health Association, served as secretary of the Indianapolis Medical Society, was a member of the staffs of the James Whitcomb Riley Hospital for Children, Methodist, St Vincent's and Indianapolis City hospitals, Indianapolis, aged 46, died, November 30 in the Barnes Hospital of bronchopneumonia

George Thomas Tyler Jr * Greenville, S C Johns Hopkins University School of Medicine, Baltimore, 1904, past president and a member of the executive committee of the Greenville County Medical Society, one of the founders' group and specialist certified by the American Board of Surgery, served in the medical corps of the U S Army during World War I, at one time operated a private hospital, served as a chief of the general surgical service, president of the staff and on several committees of the organized staff of the Greenville General Hospital for two years or more editor of the *Bulletin* of the Greenville County Medical Society, aged 66 died November 26 in the Johns Hopkins Hospital, Baltimore, of a fungous infection of the meninges

Lenna Leota Meanes, New York, Drake University Medical Department, Des Moines, Iowa, 1897, formerly clinical instructor in obstetrics at her alma mater, at one time director of the baby health conference of the Iowa State Department of Agriculture, past president of the Iowa State Society of Medical Women served on the staffs of the Salvation Army Maternity Home and the Methodist and Mercy hospitals, Des Moines, for many years medical director of the Foundation for Positive Health, Inc, author of "Exercises for Health", aged 71, died, December 4, in the Braker Memorial Home of coronary occlusion and hypertension

Harold Egbert Alexander, Saskatoon, Sask, Canada, University of Toronto Faculty of Medicine, 1910, F R C S, Edinburgh, Scotland, 1925, fellow of the American College of Surgeons, attending surgeon, St Paul's and City hospitals, aged 58, died, October 5

Francis Marion Barton, Willisville, Ark, St Louis College of Physicians and Surgeons, 1910, aged 73, died, November 25, of prostatitis and cystitis

Phebe Anderson Bottorf, Kalispell, Mont, Hahnemann Medical College and Hospital, Chicago, 1894, aged 80, died, November 16, in Los Angeles of cerebral hemorrhage

John D Bryant, Fayetteville, Tenn, University of Tennessee Medical Department, Nashville, 1890, member of the Tennessee State Medical Association, aged 75, died, November 24, of coronary heart disease

Edwin Martin Bullwinkel, Brooklyn, Long Island College Hospital, Brooklyn, 1898, member of the Medical Society of the State of New York, aged 65, died, October 10

Martin Francis Burns, Port Washington N Y, College of Physicians and Surgeons, New York, 1895, aged 73, died, November 15, of acute coronary occlusion

Matthew Campbell * La Crescenta, Calif, L R C P and S, Ireland, 1904, served as a captain in the medical corps of the U S Army during World War I, aged 68, died, November 10, in the Glendale (Calif) Sanitarium of coronary thrombosis

Samuel Victor Carmichael, Strome, Alta, Canada, Queen's University Faculty of Medicine, Kingston, Ont, 1908, aged 60, died, October 27, of a heart lesion

Barrett Conner Catlin, Baltimore, Southern Homeopathic Medical College Baltimore, 1895, at one time associate professor of obstetrics at his alma mater, formerly chief of the eye clinic, obstetrician and secretary of the board of directors of St Luke's Hospital, aged 74, died in November

John Coulter Cheeseman, Ingram, Pa, Miami Medical College, Cincinnati, 1878, member of the Medical Society of the State of Pennsylvania, aged 95 died November 24, of hypostatic pneumonia following an old cerebral hemorrhage

Ratford Frank Childs, Audubon Iowa, Omaha Medical College 1897, member of the Iowa State Medical Society, associate on the staff of the St Anthony Hospital, Carroll, aged 68 died, November 19, of coronary thrombosis

Carter James Crippen, Constable, N Y, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878, aged 90, died, November 12, of bronchopneumonia

Alfred W Crozier, Pittsburgh, Western Pennsylvania Medical College Pittsburgh 1904, member of the Medical Society of the State of Pennsylvania, served as a lieutenant in the medical corps of the U S Army during World War I, formerly a member of the staff of St Francis Hospital, aged 63, died, November 9, of chronic myocarditis and coronary occlusion

James Taylor Davis, Elizabeth N J Howard University College of Medicine, Washington D C 1920, member of the Medical Society of New Jersey, aged 52 died November 21, of heart disease

Ephraim Elmer Ellsworth * Ironton Ohio, University of Louisville (Ky) Medical Department 1894, formerly secretary of the Lawrence County Medical Society, on the staff of the Charles S Gray Deaconess Hospital, aged 78 died November 12

Charles Cowdrey Fitts, Carrollton, Ga Emory University School of Medicine Atlanta, 1917, member of the Medical Association of Georgia served during World War I, head of the medical unit of the county civilian defense board and until recently chief examiner of the local draft board, aged 48, died, November 8

Thomas H Flynn * Somerville, N J, Albany (N Y) Medical College 1890, past president of the Somerset County Medical Society, on the emeritus staff of the Somerset Hospital, for many years director of the Second National Bank of Somerville, aged 85 died, November 27, of chronic myocarditis

William Martin Garner, Rosston Ark, University of Arkansas School of Medicine, Little Rock 1911, member of the Arkansas Medical Society, aged 59, died, November 19, of cirrhosis of the liver

Lester McCutcheon Githens, Wren, Ohio, Eclectic Medical College, Cincinnati 1921, served during World War I, aged 47, died, November 16, in the Adams County Memorial Hospital, Decatur, Ind, of uremia

William Laurence Gray, Seattle, Vanderbilt University School of Medicine, Nashville, Tenn, 1901, aged 69, died, November 11, of coronary embolus

Sergius Alexander Hartman, Milwaukee, University of Moscow Faculty of Medicine, Russia, 1895, aged 73, died, November 13, of chronic cardiovascular disease

Charles Henry, Pleasant Plain, Iowa State University of Iowa College of Medicine, Iowa City, 1886, also a pharmacist, for many years a member of the U S Pension Board, aged 82, died, November 23, in Ottumwa of arteriosclerosis

Robert G Herring, Martinville, Ark, University of Arkansas School of Medicine, Little Rock, 1901, aged 83, died, November 30, of pneumonia

Nathan J Hughes, Waverly, Ill., Cincinnati College of Medicine and Surgery, 1879, University of the City of New York Medical Department, 1890, for several years was on the Waverly township high school board of education, aged 88, died, November 18, of cerebral hemorrhage

Herbert S Hutchinson, Milford, N H., Bellevue Hospital Medical College, New York, 1880, member of the New Hampshire Medical Society and for fifty years' membership in the society received a gold medal in 1932, aged 93, died, November 26

Amanda Elizabeth Ingraham ♂ Wethersfield, Conn., Tufts College Medical School, Boston, 1900, member of the American Academy of Pediatrics and of the New England Pediatric Society, at one time founded a hospital and organized a training school for nurses for the Serbian government, director of the bureau of child hygiene of the Connecticut State Department of Health at Hartford from 1923 to 1936, aged 68, died, November 26, of heart disease

Joseph Clinton Irvine, Denver, Homeopathic Hospital College, Cleveland, 1884, aged 84, died, November 18, of bulbar paralysis

Edward Joslin ♂ Whitehall, N Y., Albany Medical College, 1891, village health officer of Whitehall from 1922 to 1939, aged 74, died, November 24, of carcinoma of the sigmoid

John Alexander Lane ♂ Eureka Calif., Cooper Medical College, San Francisco, 1898, aged 68 died, November 11, in St Joseph Hospital of coronary thrombosis

George Mitchell Lochner, St Petersburg, Fla., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909, member of the Florida Medical Association, served overseas as a captain in the medical corps of the U S Army, surgeon general of the National and Florida Veterans of Foreign Wars, aged 56, died, November 17

Eugene Y Malone, Trussville, Ala., Medical College of Alabama, Mobile, 1892, served during World War I, aged 73, died, November 25, of angina pectoris

Frank F Martin, Roosevelt, Okla., St Louis College of Physicians and Surgeons, 1907, aged 62, died, November 17, in the General Hospital, Hobart, of a kidney infection

Orson Eugene Matter, Maywood, Ill., Chicago Homeopathic Medical College, 1896, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1904, member of the Illinois State Medical Society, aged 70, died, December 3, in the Oak Park (Ill.) Hospital of arteriosclerosis

Frederick Aaron Meisle ♂ Philadelphia Jefferson Medical College of Philadelphia 1904, aged 62, died, November 21, in the Jefferson Hospital

William George Moorehouse, Lancaster, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1885, formerly a medical examiner for the Pennsylvania Railroad, aged 80, died, November 20, in the Lancaster General Hospital of a fracture of the right femur as the result of a fall, pneumonia and arteriosclerosis

Charles Samuel Noble, Seattle, New York University Medical College, New York, 1896, aged 67, died, November 15

Dorothy Kathryn O'Connor, Riverside Ill., University of Illinois College of Medicine, Chicago, 1938, member of the Illinois State Medical Society, aged 31, died, November 20, in St Luke's Hospital, Chicago

Edward R Palmer ♂ Ashland, Ky., University of Louisville Medical Department, 1896 past president of the Jefferson County Medical Society, the Louisville Society of Medicine and the Louisville Urological Society, at one time vice president of the Kentucky State Medical Association, formerly professor of physiology at his alma mater, aged 70, died, November 25

Ernest Boring Porter ♂ Altadena, Calif., Northwestern University Medical School, Chicago, 1925 fellow of the American College of Physicians, formerly health officer of Coronado, served during World War I, captain, medical reserve corps, U S Army, not on active duty, on the staff of the Mercy Hospital, San Diego from 1927 to 1938, aged 47, died November 15, of coronary thrombosis

Moses D Rabenoyich, Toledo, Ohio, University of St Vladimir Faculty of Medicine, Kiev, Russia 1879, aged 84, died, November 25, in the Toledo Hospital of hypostatic pneumonia following a fracture of the left femur due to a fall

Florence Stephen Richard, Shreveport, La Tulane University of Louisiana School of Medicine, New Orleans, 1919, aged 49, died, November 11

Alexander Peter Robertson ♂ Alton, Ill., National University of Arts and Sciences Medical Department, St. Louis, 1913, past president of the Madison County Medical Society, served in the medical corps of the U S Army during World War I, at one time health commissioner of Alton, for seventeen years director of the Social Hygiene Clinic aged 52, on the staff of the Alton Memorial Hospital where he died November 20, of ruptured aneurysm of the aorta

Frank Augustus Ross ♂ South Berwick Maine, Medical School of Maine, Portland, 1896, aged 69, died, November 16, of cerebral hemorrhage

Benson Ruddell, Frankfort, Ind., Medical College of Indiana, Indianapolis, 1900, member of the Indiana State Medical Association aged 66, died November 24, of carcinoma of the cervical glands of the left side of the neck

S P Ruff, Marshall, Ark (licensed in Arkansas in 1903), aged 82, died, November 26 of lobar pneumonia

Edwin Stanton Saylor, West Point Pleasant, N J University of Pennsylvania Department of Medicine, Philadelphia, 1898, member of the Medical Society of the State of Pennsylvania, at one time chief of ophthalmology at St Timothy's Hospital and on the staffs of the Wills, Pennsylvania and Polyclinic hospitals, Philadelphia, formerly lecturer on diseases of the eyes and ears at the American Stomach Hospital, Philadelphia, served during World War I, aged 76, died, November 23, in Laurelton of myocarditis

Ernest Schemer, Grand Rapids, Mich., Detroit College of Medicine, 1894, aged 84, died, November 18, of senility

William H Slattery, Lincoln, Neb., St Louis College of Physicians and Surgeons, 1902, formerly city physician, a member of the executive board and active member on the committee of internal medicine of St Elizabeth Hospital, aged 70, died, November 17, of diabetes mellitus

Louis E Slayton, Spencerport, N Y., University of Vermont College of Medicine, Burlington, 1884, aged 80, died November 29, in Cazenovia of arteriosclerotic cardiorenal disease

Henry Hutchison Taggart, Wichita, Kan., Kansas City (Mo.) Medical College, 1900, formerly secretary of the staff of the Wichita Hospital, aged 68, died, November 9

Frederick Llewellyn Thomson, San Antonio, Texas, McGill University Faculty of Medicine, Montreal, Que., Canada, 1896 member of the Bexar County Selective Service Board number 9, aged 68, died, November 17

Achilles Douglas Tyree, Clifton Forge, Va., Medical College of Virginia, Richmond, 1911, member of the Medical Society of Virginia, served as a captain with the British Expeditionary Forces in France during World War I, aged 52, died, November 12

Herbert Dutton Weaver, Saskatoon, Sask., Canada, Trinity Medical College, Toronto, Ont., 1897, for several years lectured at the Dalhousie University Faculty of Medicine Halifax N S., aged 75, died, September 12, in St Paul's Hospital

James L Wells, Chicago, Harvey Medical College, Chicago, 1902, member of the Illinois State Medical Society, formerly on the staff of the Englewood Hospital, aged 72, died December 14, of coronary thrombosis and hypertension

Carolyn Louise Westlake Widdowson, Le Roy, N Y University of Buffalo School of Medicine, 1897, aged 69 died, November 3

DIED WHILE IN MILITARY SERVICE

Frank Clinton Andrus ♂ Minneapolis University of Minnesota Medical School, Minneapolis 1933, specialist certified by the American Board of Pathology Inc, member of the American Association of Pathologists and Bacteriologists and of the American Society of Clinical Pathologists, assistant professor and formerly teaching fellow in the department of pathology at his alma mater, at one time instructor of pathology at the Ohio State University College of Medicine Columbus in April 1938 was appointed director of the laboratory of the Springfield City Hospital, in September 1939 was made director of the laboratory of the Minneapolis General Hospital, captain in the medical corps, Army of the United States, chief of the laboratory service of the Percy Jones General Hospital Battle Creek, Mich., aged 35, died, November 14 in Battle Creek, Mich., of coronary occlusion

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

Ambrew Mate Institute—Under this trade style in Adna E. Hall of New York started in 1933 an enterprise then limited to the sale of Ambrew Mate Tea, a proprietary name for a plant leaf product from South America. That period it will be recalled was the heyday for exploiting mate (under proprietary names) as a tonic and many other things. Around 1937 Hall went into the hair growing business. In his advertising he quoted from what he described as a newspaper feature article written in 1937 by George Jean Nathan, dramatic critic, in which Mr. Nathan is supposed to have claimed that fifteen years earlier when some of his hair had fallen out after an attack of influenza an English sea captain who had a head of hair at sixty-two that looked like the Wild Man of Borneo's told him that the heavy growth was due to application of the juice of the mullein plant whereupon the critic tried the stuff himself and obtained similar results as did scores of his personal friends. The story was dealt with in a current comment in THE JOURNAL, April 10, 1937, page 1266. From the newspaper article Hall claimed to have got the inspiration for an alleged hair grower and proceeded to market it under the name Lotta-Lov, which a government chemist found to be a mixture of 2.6 Gm. of mullein with glycerin and rosewater. Hall's representations for this as a cure for baldness did not convince the Post Office Department which after an investigation notified him to show cause on Jan. 9, 1942, why the mails should not be closed to his business on the ground that it was fraudulent. Hall did not appear at the hearing on that date but sent his attorney. An expert medical witness for the government testified that many cases of falling hair and baldness are due to systemic causes not remediable by external application of local tonics and that the commonest form of permanent baldness, alopecia prematura, is due to hereditary factors and not amenable to any known treatment; that in alopecia areata the hair may return in course of time without artificial aid and that in senile alopecia or baldness of old age resulting from progressive loss of hair due to atrophy of hair follicles there could be no restoration of hair growth. It was further shown that Hall's mullein mixture would have no effect on systemic causes of baldness or in any way bring about a growth of new hair or stop excessive hair loss. The witness dismissed the testimony credited to Mr. Nathan for the efficacy of mullein in baldness with the opinion that the regrowth of hair if any was due not to the mullein but to time and time alone. In spite of the defense attorney's contention that Hall's advertising contained no representation or promise as to the curative power of Lotta-Lov and that the government's expert medical witness was not qualified to pass on the merits and action of the product without having personally used or prescribed it, the preponderant evidence at the hearing was that the business amounted to obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. The Post Office accordingly issued a fraud order on May 6, 1942, against the Ambrew Mate Institute and its officers and agents.

David Aitchison—From Arlington, Va., this person sold a cancer cure through the mails and styled himself M. D. D. M. L. D. In December 1941 the Post Office Department notified him to show cause at a hearing to be held on Jan. 16, 1942, why a fraud order should not be issued against him. Neither Aitchison nor any one representing him put in an appearance but subsequently he sent the Post Office a statement commenting on what had taken place at the hearing. The gist of the evidence presented there and of Aitchison's communication as reported is given in the following abstract of the Post Office memorandum of this case. Aitchison solicited business by means of advertisements placed in periodicals circulating through the mails. One of these read: "Cancer treated successfully by the famed Street method. (Whatever that was)." To inquirers Aitchison sent handwritten questions regarding their physical condition and from their replies he pretended to diagnose their cases after which of course he recommended his treatment at various prices ranging from \$25 to several hundred dollars. It appears that he prescribed for a variety of disorders. His cancer treatment consisted of three preparations called "No. 36," "No. 52," and "Rectum." Government chemists reported on these as follows: "No. 36" a gray uncoated tablet of 3.1 grains containing milk sugar, lactose hydrate and 1/10 grain of charcoal. "No. 52" a powdered material containing senna leaves, buckthorn bark, alfalfa leaves and stems, caraway seed and about 10 per cent of sodium sulfate. "Rectum" (rectal injection) a hydroalcoholic solution containing 17 grains of plant extractives per hundred cubic centimeters with no minerals or alkaloids. The medical witness at the hearing, an eminent authority on cancer, testified that this combination of medicines would have no value whatever in the treatment of any type of cancer nor would Aitchison's recommendation of diet, exercise and rest eliminate or even check a cancerous condition. It was brought out that although Aitchison claimed to be licensed as a doctor of naturopathy in Maryland, Virginia and Tennessee, the authorities of those states denied this. Among other evidence submitted at the hearing was a certified copy of a record of the District of Columbia Police Court showing that Aitchison had been convicted on Nov. 1, 1922, of practicing medicine in that district without a license and sentenced to pay a fine of \$1,000 or serve 90 days in jail. It was further shown that though Aitchison claimed to

be a graduate of the National College of Therapeutics, a school which he stated had specialized in naturopathy but which is no longer in existence, he had had no recognized medical training and so far as the evidence showed was not licensed to practice medicine or any other method of healing anywhere in the United States. Neither did his communications to the Post Office Department offer any evidence to support his claim that he had cured many cases of cancer. Accordingly a fraud order debarbing his business from the mails was issued on Feb. 23, 1942, against the various designations under which he had operated.

Glamo Form Products—This was the trade style used by a Brooklyn concern which sold through the mails an alleged bust developer known as 'Glamo Form'. This was sold for \$1 with the promise that when used as directed it would enlarge and reshape flat undeveloped breasts and provide the user with a beautiful bust line and further would develop unsightly and thin legs into legs with beautiful symmetrical proportions. The Glamo Form concern was said to be receiving about 100 pieces of mail daily at the time that the Post Office notified this company to show cause on Feb. 5, 1942, why it should not be debarred from the mails for operating a fraud. The defendant company denied the charges alleging that what it actually offered was a course of treatment consisting of advice on massage and brassieres and that the entire course was not confined to the use of its massage cream. No one representing the concern appeared at the hearing, however, to testify that it was engaged in selling brassieres. On the contrary, the evidence presented clearly showed that the only product actually intended to be sold was the massage cream. In fact it was shown that the promoters sold the cream to women who wrote in that they desired this product if it would provide them with a beautiful bust line in place of breasts that had been flat and flabby for years. The cream, according to government chemists, was nothing more wonderful than a mixture of oils, fats and wax with 10 per cent of water and 15 per cent of camphor. An expert medical witness for the government testified at the hearing of this case that the cream of itself would neither build up flat flabby breasts nor reduce those which were large and pendulous, nor would the accompanying recommended exercises accomplish this result. This testimony was even confirmed by the defendant's medical witness, an unnamed Brooklyn physician, whose admission of those facts must have given scant support or comfort to the concern that had hired him. Altogether the evidence showed that the Glamo-Form business was a scheme to obtain money through the mails by means of false and fraudulent pretenses, representations and promises and it was accordingly debarred from the mails by a fraud order issued on March 27, 1942, against the names Glamo Form and Glamo Form Products of Brooklyn and their officers and agents.

Hairtone Company and Marvel Company—Of the making of many hair growers, as with books, there is no end. The one that was exploited under the name Quinine Hair Marvel by a Matilda Richman of Brooklyn first doing business as the Marvel Company and later as the Hairtone Company was another to come under the scrutiny of the Post Office Department. If one could believe the claims made for it, this product when used as directed would overcome the most obstinate case of baldness, eliminate dandruff and grow moustaches and eyebrows like magic. A government chemist's report on it, however, was somewhat disillusioning, showing that it was merely a mixture of substances used for years in hair growers which never grew any hair, petroleum, a trace of a vegetable oil, about 1 per cent of sulfur and less than 1 per cent of quinine. In time the product seems to have been changed over to liquid form under a new designation, Quinine Hairtone with Olive Oil, which according to its exploiter contained salicylic acid and quinine sulfate, 1 grain each, betanaphthol, 1 grain, resorcinol, 2 grains, sulfur, 20 grains, olive oil, 8 minims, and castor oil, 30 minims. Thus the name of the preparation was misleading since the mixture contained more castor oil than olive oil. Not for this reason but because of other false and misleading representations under which it was sold the Post Office Department after due investigation of the scheme ordered the promoter of the Hairtone Company and Marvel Company to appear at a hearing on Jan. 30, 1942, and answer charges of conducting a mail order fraud. Her attorney appeared for her. An expert medical witness for the Post Office described at some length the various causes of baldness (with which the defendant's medical witness, a Brooklyn physician whose identity was not disclosed in the memorandum on the case, agreed) and further showed that the treatment in question would have no value in removing or correcting these conditions. Also without weight the government charged was the contention of the defendant's counsel that Matilda Richman had not intended to represent her preparations as a treatment for baldness or to give the impression that the use of the product will grow hair, unless the hair roots are actually alive. The government disproved this claim of the attorney by showing that in at least one instance Matilda Richman had sold her Quinine Hair Marvel to an inquirer who had described himself as almost completely bald and who had specifically stated that he wanted the preparation if it would grow new hair on the bald spots. In view of the preponderant evidence that the treatment did not justify the representations made for it, the business was debarred from further use of the mails by a fraud order issued on May 22, 1942, against the names Hairtone Company and Marvel Company and their officers and agents.

Nu Hair Products—Under this trade style one Joseph Vallon operated from New York and Brooklyn in selling an alleged hair grower through the mails. It was known as Complete Nu Hair Scalp Treatment and comprised the 'Besgro Formula', 'Pressing Compound' and 'Special Shrimpo'. If one could believe the advertising these would cure head sores and sears, prevent loss of hair and grow long healthy hair on the head of any person who was bald. There was the additional promise that great success has been reported in most obstinate cases. In view of these claims the Post Office Department notified the concern to show cause on January 27, 1942, why a fraud order should not be issued against it. On that date the concern's attorney appeared at the hearing. A qualified chemist testified that his analyses had shown the following compositions: Nu Hair Besgro, an opaque yellow salve con-

trimming petrolatum 6.55 per cent of sulfur and a small amount of wool fat, Nu Hair Pressing Compound a slightly perfumed amber colored petrolatum salve, Castile Shampoo a granular soap powder with no medication. The chemist added that he did not find the quinine and balsam peru claimed to be present in the Nu Hair Besgro. An expert medical witness testified for the government that though the sulfur in this product would destroy parasites in the hair and scalp and that the ointments would tend to soften the epidermis of the scalp with the shampoo acting as a cleanser the treatment as a whole would be of no value for any systemic cause of baldness or falling hair and this fact also was admitted by the defendant's witness. This was a Dr Edward Podolsky of Brooklyn who confessed that he was not a dermatologist. Podolsky is, however, known to have promoted the sale of various fad foods. Eventually the Nu Hair Products and their officers and agents were debarred from the mails by a Post Office fraud order issued on March 9, 1942.

RESUSCITATION OF THE NEWBORN

To the Editor—With regard to resuscitation of the newborn, almost all students of the subject advocate tracheal intubation. This is a simple operation if the proper directions are followed.

First, one needs a semirigid catheter of latex or some similar substance of approximate size F 12. The tracheal end preferably should be beveled and all surfaces emery papered smooth. Its length of about 8 inches has been found satisfactory. For the past several years, students of the University of Georgia School of Medicine have been taught tracheal intubation by practice on a recently delivered stillborn infant. The technic is so simple that each of a class of forty is able to intubate the trachea during a one hour period. This includes exposure of the trachea by direct laryngoscopy with an electric lighted infant laryngoscope, of which several inexpensive models are on the market. With the epiglottis held anteriorly by the laryngoscope blade, while the infant lies supine on a flat surface, the catheter is gently inserted into the round tracheal opening which lies immediately anterior to the larger esophageal cavity. The catheter is inserted about 2 inches and then the insufflator is attached to the other end.

We have found satisfactory a simplified De Lee type of mouthpiece insufflator with an added weighted valve which automatically prevents too much pressure to the lungs (Volpitto, P. P., and Torpin, Richard. *Apnea Neonatorum Its Treatment by a Simplified Insufflation Technic*, *South M J* 35:559 [June] 1942).

There is little doubt that many infants could be made to breathe that never do, and that many who die in the first week or so of life from pneumonia probably obtain the infection from inspiration of infected secretions at the time of birth.

RICHARD TORPIN, M.D., Augusta, Ga.

"JEJUNAL ULCERS AND RECURRENT HEMORRHAGES AFTER PARTIAL OR SUBTOTAL GASTRECTOMY"

To the Editor—The article by E. D. Kiefer on this subject (*THE JOURNAL*, Nov. 14, 1942) may change the whole aspect of surgical treatment of duodenal ulcer. If radical operation is followed by jejunal ulcer in as many as 7 per cent of the cases then our conception that gastrectomy is superior to gastroenterostomy has to be revised.

However, an analysis of the 12 cases reported in Dr. Kiefer's paper does not permit the assumption that the results of radical operation in duodenal ulcers are "tragically disappointing" as far as postoperative jejunal ulcers are concerned.

As a matter of fact, in 7 of the 12 cases no radical operation but Finsterer's method was used, and according to a personal communication of Dr. Kiefer in 2 cases of the remaining 5 gastric resection was done not for duodenal ulcer alone but for duodenal ulcer plus gastroenterostomy plus jejunal ulcer.

In the 30 cases of Dr. Kiefer's series in which the Finsterer operation was done, it must be appreciated that in this method the ulcer, the pylorus and part of the antrum are not included in the resection. In 7 of these 30 cases jejunal ulcers subsequently developed. The first disappointing results of the Finsterer procedure were published as far back as 1932 (a bibliography is presented in an article on technical procedures in the *Journal of the International College of Surgeons* 5:1 [Jan.-Feb.] 1942). Dr. Kiefer is quite correct in stating that "any procedure that does not remove the pylorus and the duodenal ulcer is inadequate," as it is not a radical operation.

As to the 2 patients who had duodenal ulcer plus gastroenterostomy plus jejunal ulcer, in them the question of primary radical operation for duodenal ulcers is not involved. Those marginal ulcers which recur even following partial gastrectomy are frequently looked on as "surgically incurable." That designation is not entirely justified. However, it is most probable that these "incurable" ulcers are not primarily incurable but that insufficient surgical intervention such as gastroenterostomy or the Finsterer operation results in an irritative condition which later makes the ulcer refractory to any medical or surgical therapy.

In view of the fact that jejunal ulcer (only one verified by operation) developed in only 3 cases out of at least 115 in which primary resection was done, I would call these results fairly satisfactory rather than disappointing.

RUDOLF NISSEN, M.D., New York

ANDROGENS AND TESTICULAR IRRADIATION IN CANCER OF THE PROSTATE

To the Editor—In discussion of a recent group of papers on prostatic cancer, Munger (*THE JOURNAL*, Dec. 5, 1942, p. 1120) said "The theorem of possible relationship of some factor in the testicle, probably androgenic, to carcinoma of the prostate was promulgated by me eight years ago." The quotation refers apparently to an oral promulgation rather than a publication, since no reference to it could be found in the papers of Dr. Munger cited before 1941 in the *Quarterly Cumulative Index Medicus*, a source which most workers accept as indicating publication in the clinical fields of medicine. The first paper proving any relationship between hormones and cancer of the prostate gland was published by Huggins and Hodges (*Cancer Research* 1:293 [April] 1941), who showed that cancer of the prostate is activated by androgen injections and is inhibited by eliminating androgens through castration or neutralization of their activity by estrogen injection. These conclusions have since been confirmed in many published reports.

Some months ago the effect of irradiation of the gonads was described by Munger (*J. Urol.* 46:1007 [Nov.] 1941), who concluded that "a study of several cases treated by testicular irradiation with [prostatic] resection seems to indicate that slightly better results were obtained than in those cases treated by resection and x-ray exclusive of the testicular application." This appears to me to be a fair statement of the results. Many observers have reported that extensive irradiation of the testes of animals does not eliminate androgen production by these glands, although the germinal epithelium is destroyed. Moreover, consonant with the experimental findings, the observations of Gutman (*THE JOURNAL*, Dec. 5, 1942, p. 1112) and of Huggins (*Ann. Surg.* 115:1192 [June] 1942) indicate that orchiectomy has produced clinical benefit in cases of prostatic cancer in which testicular irradiation had been administered previously in sterilizing amounts with unsatisfactory clinical results. Roentgen irradiation of the testes appears to be inadequate as a therapeutic agent in human prostatic cancer.

Tennessee June Report

The Tennessee State Board of Medical Examiners reports the written examination for medical licensure held at Knoxville, Memphis and Nashville June 17-20, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. One hundred and eighteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists	(1942)	(1942)	1
Howard University College of Medicine	(1941)	(1941)	1
University of Minnesota Medical School	(1942)	(1942)	1
Long Island College of Medicine	(1942)	(1942)	1
University of Buffalo School of Medicine	(1924)	(1924)	1
Jefferson Medical College of Philadelphia	(1941)	(1941)	1
University of Pennsylvania School of Medicine	(1942)	(1942)	2
Meharry Medical College	(1942)	(1942)	47
University of Tennessee College of Medicine (1941)	(1942)	(1942)	19
Vanderbilt University School of Medicine	(1942)	(1942)	42
McGill University Faculty of Medicine	(1940)	(1940)	1
American University of Beirut School of Medicine	(1940)	(1940)	1

Ten physicians were licensed to practice medicine by reciprocity from June 13 through Aug 5, 1942. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Emory University School of Medicine	(1941)	(1941)	Georgia
University of Kansas School of Medicine	(1939)	(1939)	Kansas

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Death from Rocky Mountain Spotted Fever Caused by Bite of Wood Tick Allegedly Received in Course of Employment—Prowse worked in the waste dump of a mine, parts of which were overgrown with foliage. On July 22 he told his foreman that while at work something had bitten him on the finger and that he had brushed it off. Apparently for the next few days he did not feel well and was "irritable and grouchy." On the 26th he became "ill" and was hospitalized on the 29th. On the 31st Rocky Mountain spotted fever was diagnosed, from which he died August 2. Alleging that Prowse's death was due to the bite of a wood tick suffered in the course of his employment, the widow instituted proceedings for compensation before the industrial commission of Utah. From an award in the widow's favor the employer appealed to the Supreme Court of Utah.

The sole question to be determined by this court, said the Supreme Court, is whether the evidence before the industrial commission was sufficient to sustain its findings that the workman received the fatal tick bite during the course of his employment. Rocky Mountain spotted fever is a disease of man directly traceable to a deadly virus carried by infected wood ticks. These infected transmitting agents attach themselves to man by biting. The virus becomes reactivated within several hours after ingestion of blood in the tick has begun, and it is then passed into the body of man. There are two types of infection in man—ambulatory and fulminating. The workman was diagnosed as having the latter and more fatal infection. The period of incubation within man covers a period of from two to fifteen days, depending on the severity of the infection, the resistance of the man and the locality of the bite. In cases of fulminating infections, the period of incubation is determined as from two to five days, the prodromal period is from two to three days in duration during which time the characteristic chilly sensations, backache and the like appear. These sensations first experienced by Prowse on July 26. Death occurs between the ninth and fifteenth day following infection. It is not infrequent that the site of the tick attachment cannot be found. Medical science has some basis for the belief that the virus of an activated tick may enter through the pores of the skin.

A physician called as a witness by the employer testified that in his experience no tick has ever bitten a man on the hand but that their tendency is to seek a locality on the body where they are not so apt to be brushed off. Because of this testimony the employer contended that the industrial commission could not properly find that the tick bite was suffered by the workman during the course of his employment, since such a finding is a mere surmise, conjecture, guess or speculation. The Supreme Court however, adverted to the direct testimony of the employer's foreman that the deceased had complained to him of a bite on his finger during working hours. Thus, said the court, created a conflict in the testimony sufficient to justify the finding of the commission, regardless as to whether or not this court would have arrived at the same conclusion or inference from the testimony as was arrived at by the industrial commission. The duty of this court in the presence of conflicting evidence is to examine the record, and, unless we can say that as a matter of law the conclusion of the commission was wrong because only the opposite conclusion could be drawn from these facts, this court must affirm the finding of the commission.

The employer contended that there are instances in which, even though an opposite conclusion cannot be drawn, the commission cannot conclude that the accident arose in the course of the employment. This, it was argued, is the situation where the commission cannot from all the facts infer the ultimate fact that the accident occurred in the course of the employment with any more probability than that it occurred outside of the course of employment. "To infer," answered the court, means "to bring into, to bring forward" (Webster's International Dictionary, second edition). The very process of inference involves the process of one fact or a set of facts pushing forward in the mind the probability of the inferred fact. Sometimes the basic fact or facts from which the inference arises strongly urge to any reasonable mind the inferred fact. At other times, the process of inference is more tenuous. And true it is that, where the fact attempted to be inferred is pushed or carried out of the basic facts with no more urgency than some other fact, the inferences are said to be equal and cancel each other. Perhaps the more accurate way to state the proposition is that the mind in its natural functioning does not bring forward any fact from the underlying facts because, being in a condition of equipoise, no inferable fact is brought forward or pushed out of the underlying facts as a natural conclusion. The question arises, Have we such a situation in this case? The employer urged that testimony to the effect that wood ticks are found in the entire intermountain region in which the workman lived and worked, together with testimony to the fact that he went on a picnic in the mountains and swimming within the intermountain region, puts the mind in a condition of equipoise as to the event of the accident at which it must remain. But, said the court, from the fact that ticks are found in the entire intermountain region it does not follow that they are found in equal abundance all over the region nor that the facilities for the workman to contract them were equal in all the places he chanced to be in the intermountain region during any possible period of incubation. The facts were that Prowse's work took him into brush to an extent not ordinarily to be expected while at home, swimming or even on a picnic. Moreover, four witnesses testified to the actual presence of ticks at a point 3 miles from where Prowse worked. The conditions that existed in the locality where the witnesses saw the ticks were practically the same as the conditions at the place where the deceased worked. In view of these facts, we can assume that there were ticks where Prowse worked, thus tending to show the actual presence of ticks in the locality of Prowse's work in contradistinction to the entomologic fact which we all know that ticks exist throughout the intermountain region. But one further potent piece of evidence is sufficient in view of the evidence just recited to throw the mind off equipoise. It has been established that in cases of fulminating infection the period of incubation is from two to five days. Here Prowse became ill on July 26, the period of incubation extending back to the fifth day from that date, or to July 22, the date on which Prowse complained of a bite. During this period he was off work on July 24, a holiday. From the record it appears that he remained at home on this

day The remaining days during this period of incubation he spent at his work, traveling between his home and work, and at home There is nothing appearing of record which is intrinsically discrediting to the uncontradicted testimony of the witnesses nor is such testimony wholly from interested witnesses Furthermore, the evidence as appears in the record not only carries "a measure of conviction" to the reasonable mind but is sufficient to throw the mind off equipoise, raising the inference that the deceased picked up the tick in the course of his employment

For the reasons stated, the award of the commission in favor of the widow was affirmed—*Salt Lake County v Industrial Commission, 120 P (2d) 321 (Utah, 1941)*

Harrison Narcotic Act Unlawful Sale by Physician, Bona Fide Medical Practice—The defendant, a practicing physician, was charged with a violation of the Harrison Narcotic Act in that he had unlawfully sold morphine sulfate, a derivative of opium The evidence showed that the defendant had from time to time delivered morphine to certain persons without use of the order form prescribed by law and that the defendant gave no directions, either verbally or in writing as to how the drug should be taken The two morphine deliveries specifically set forth in the indictment were made at night in secluded places on the streets of Atlanta, Ga As to one of these, witnesses for the government testified that it was made after dark in a secluded place on the street near a school building Government officers watched while the sale and delivery was being made, the officers having furnished the \$5 which was used by another person to purchase the morphine from the defendant When the sale and the delivery had been consummated, the officers took possession of the morphine and arrested the defendant The \$5 was identified by serial numbers and dates as being the same money furnished by the officers, and a quantity of morphine was found in the defendant's possession From a judgment of conviction, the defendant appealed to the U S circuit court of appeals, fifth circuit

The defendant contended that the sales were made in connection with the bona fide practice of medicine What constituted bona fide medical practice, the court said must be determined on consideration of the evidence and attending circumstances In the present case, the evidence was such that the jury could properly conclude that curbstone sales of morphine as charged in the indictment were not made in connection with a bona fide medical practice but that they were in fact unlawfully made The evidence, the court concluded, made a case for the jury, and the trial court properly refused to direct a verdict in favor of the defendant physician The court also found that there had been no error committed in the admission or exclusion of evidence during the trial, that the evidence was sufficient to support the verdict and that no reversible error existed Accordingly the judgment of conviction was affirmed—*Moore v United States, 128 F (2d) 887 (1942)*

Taxes Exemption from Occupational Tax Law, When a Physician "Practices" His Profession—The defendant was licensed to practice medicine in Louisiana in 1929 and immediately entered the United States Public Health Service and was assigned to the United States Marine Hospital, Mobile County, Ala, where he remained until his resignation from the service in June 1940 During that time he was for one year head of the department of venereal diseases, for five years he engaged in general surgery at the hospital and for the remaining period he engaged solely in the treatment of diseases of the eyes, ears, nose and throat During this entire period his only remuneration from the practice of his profession was his salary from the government In June 1940 he obtained a license to practice medicine in Alabama and opened an office in Mobile specializing in diseases of the eyes, ears, nose and throat The state brought suit against the defendant to recover certain license taxes alleged to be due it for the last half of 1940 and all of 1941, the time during which the defendant had been in private practice From a judgment for the defendant, the state appealed to the court of appeals of Alabama

The defendant contended that he was exempt from the payment of the taxes because of the following language of the

statute "Provided that the license imposed by this section shall not apply until such person shall have practiced his or her profession as long as two years" The court of appeals first pointed out that an exemption from license taxation under a constitutional or statutory provision is in derogation of common right and must receive a strict interpretation and no claim to exemption can be sustained unless it is clearly within the scope of the exempting clause The existence of an exemption will not be presumed but must be clearly proved, and if there is any doubt the uncertainty will be resolved against the exemption The plain purpose of the exemption quoted, said the court, was to aid the young practitioner in establishing himself in his profession The court could not assent to the proposition that the defendant was not subject to the tax until he had engaged in private practice for as long as two years The practice of a profession and private practice are not synonymous In the opinion of the court, the defendant was practicing medicine when he was doing general surgery in the United States Marine Hospital Medicine was his profession Therefore he was practicing his profession within the language of the statute Accordingly the court concluded that the circuit court had erred in denying the right of the state to recover the tax Judgment in favor of the defendant was reversed and judgment was entered in favor of the state Certiorari was denied by the Supreme Court of Alabama—*State v Sellers, 9 So (2d) 19, 9 So (2d) 20 (Ala, 1942)*

Chiropractors Advertising as Evidence of Unlicensed Practice—The defendant was charged with a violation of the Ohio medical practice act in that he advertised or announced himself to be a practitioner of medicine and surgery in one of its branches, to wit, chiropractic, before obtaining a certificate from the state medical board as required by law The evidence showed that the defendant exhibited on the porch of his residence a gold lettered sign reading "J D Method D C" and that inside the vestibule was a "regular clock sign" reading "Doctor is in Please be seated" The defendant admitted that these two signs were all the advertising he was doing "right now" From a verdict of guilty in the trial court the defendant appealed to the court of appeals of Ohio Lucas County

The defendant contended that such evidence was not sufficient to prove him guilty beyond a reasonable doubt and furthermore that it at most tended to prove merely an intent to practice his profession and that intent alone was not evidence of criminal conduct The court disagreed with this contention Considering this evidence as a whole and the court it sufficiently appears that not only was Method intending to practice his profession but also he was actually so engaged and surely was advertising himself as practicing medicine The finding of guilty of the offense charged was therefore sustained by the evidence and the judgment of conviction was accordingly affirmed—*State v Method, 42 N E (2d) 1013 (Ohio, 1942)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Subacute Monilia Endocarditis New Clinical and Pathologic Entity J G Pasternack Staten Island N Y—p 496

Subacute Monilia Endocarditis—The recovery of yeast-like cells from the first blood cultures of a patient with subacute bacterial endocarditis caused Pasternack to carry out further studies and identification of the micro organism. Monilia was subsequently proved to be the etiologic agent of the patient's illness. Within the last two years two strains of Monilia have been recovered from 6 cases of subacute endocarditis. In 5 of them the micro organism was identified as *Candida* (Monilia) *parakrusei* and in 1 as *Candida guilliermondii*. All the patients except the author's were diacetylmorphine addicts. Subacute endocarditis due to Monilia is a new clinical and pathologic entity. An analysis of the pathologic data of the observed cases discloses the following: The vegetations were engrafted on old sclerotic valves. In 2 cases the aortic valve was involved and in 1 the mitral. The spleen was greatly enlarged and showed massive infarcts. The kidneys showed multiple small infarcts. The brain showed meningeal and focal parenchymatous lesions. Blood cultures readily yielded a prolific growth of Monilia. The author's case presented an isolated focus of hemorrhagic infarction of the ileum, edema and petechiae of the rectal and urinary bladder mucosa.

Enterobius Vermicularis in Appendix—Schenken and Moss determined the incidence of *Enterobius vermicularis* in 1,000 consecutively removed appendices. The patients were operated on at the Charity Hospital at New Orleans between July 5 and Oct 14, 1937. The complete appendiceal content of the first 600 appendices was delivered into a test tube and thoroughly emulsified in water. The specimen was centrifugated for one minute at about 500 revolutions per minute (group 1) and for the other 400 appendices (group 2) the same procedure was employed except that centrifugation was repeated until the supernatant fluid was clear. Of all the appendices 23.3 per cent were infected with *E. vermicularis*. In group 2 42.1 per cent of the appendices from white females and 38.3 per cent of the appendices from white males were infected. The respective figures for Negroes were 10.1 and 12.8 per cent. The observations in group 2 are regarded by the authors as more accurate than those in group 1 because of the use of the improved technic.

Varioliform Eruption from Sulfathiazole A G Frank Atlanta Ga and E F Traub New York—p 737

Vitamin Therapy—O'Leary points out that certain cutaneous diseases are due to avitaminosis and that after the supplemental use of the necessary vitamin or vitamins, either by proper diet or by the administration of a synthetic form, the cutaneous signs of the disease disappear. The diseases include pellagra, ariboflavinosis or cheilosis, phrynodema, pityriasis rubra pilaris, keratosis follicularis and the so-called seborrheids (nonpellagrous eruptions) recently described by Gross. Another group of diseases in which the results of vitamin therapy are less pronounced, do not appear in all cases and are less conclusive includes lichen spinulosus, keratosis pilaris, senile vaginitis, monilia infections, rosacea keratitis, psoriasis, acne cachecticorum and "dry skin." The evidence now indicates that under certain conditions vitamins *to be effective must be in harmony or in combination, as, for example, in pellagra, in which nicotinic acid, thiamine and riboflavin is necessary to control the disease.* The author believes that other diseases, such as psoriasis, may be completely controlled when the proper combination and ratio of vitamins is found. This would probably explain some of the discrepancies in the literature and differences of opinion as to the value of vitamin therapy in dermatology. No significant benefit has been obtained with vitamins in the various cutaneous manifestations of syphilis. The most pronounced benefits occur when a dermatosis is associated with constitutional signs of avitaminosis.

Cryotherapy in Treatment of Acne Scars—Friedlander states that he noticed no improvement in the scars of acne treated with carbon dioxide slush. In 13 of the 20 patients treated the average number of treatments was thirty-seven. Cryocautery offers nothing that cannot be obtained with conventional less time consuming and less painful methods.

Syndrome Characterized by Gynecomastia—Gynecomastia, small testes, aspermatogenesis, evidence of normal to moderately reduced function of the Leydig cells, increased excretion of estrogenic substance and usually a reduced excretion of 17-ketosteroids were observed during the last four years at the Massachusetts General Hospital. Two similarly affected private patients were seen by Klinefelter and his co-workers. Estrogenic substance was increased to a degree comparable to that found in castrates. Testicular biopsies of 7 patients showed hyalinization of the seminiferous tubules and normal appearing interstitial cells. The examined mammary tissue of 4 patients showed some ductal hyperplasia with definite proliferation of the periductal connective tissue. It is probable that the gynecomastia is reversible. Testosterone propionate and progesterone have been tried without success, estradiol dipropionate caused further enlargement. Surgical removal of the breast is recommended for cosmetic reasons and, if carefully done, is an exceedingly satisfactory procedure. It seems unlikely that anything can be done to correct the aspermatogenesis. The studies support the view that the testis produces two hormones, androgen from the Leydig cells and α -hormone (inhibin) from the tubules. The gynecomastia is not due to hyperestrogenism or androgen alone, it may be due to the combination of androgen and lack of inhibin.

Estrogen Treatment of Acne—Lawrence and Werthessen used estrogen in the treatment of acne of 14 women and 11 men. Only 3 of the women and 4 of the men were less than 20 years of age. The average age of the women was 25.8 years and that of the men 20. It seems unlikely, therefore, that spontaneous remission can be an important source of error in evaluating the results of estrogen therapy. The duration of the acne varied from one to thirty years. Seven of the women complained of severe dysmenorrhea, 8 of hypomenorrhea and 2 of menorrhagia. Thirteen had definite exacerbations of the acne at the time of menstruation. Diethylstilbestrol or ethinyl estradiol was taken orally. The initial dose of the former was 0.5 mg daily until tolerance was determined. Medication of women was omitted four days before the predicted menstrual period and resumed forty-eight hours after menstruation had ceased. Ethinyl estradiol was given in daily doses of 0.15 mg and increased to 0.3 mg if the response was unsatisfactory. Fifteen of the 25 patients became entirely free from acne after two to six months of treatment, 2 whose treatment was intermittent became free in eight and nine months and the remaining 8 are still under treatment, all show improvement. All the female patients (but 1 with hirsutism) have shown a synchronous improvement, comparable to the response of the acne, in menstrual difficulties. The biologic and recent experimental evidence and the results of adequate estrogen therapy suggest that acne is caused by a disturbance of the normal functional balance between androgens and estrogens when the preponderance of the androgenic factor becomes sufficient to exert its specific acneogenic effect in a given individual.

- Tetany in the Severely Traumatized Newborn W R Shannon St. Paul —p 884

Hypersensitivity to Thiamine Hydrochloride—During the past year Eisenstadt encountered 2 cases of hypersensitivity to thiamine hydrochloride given parenterally. Even after the allergic reaction (local anaphylaxis in 1 and angioneurotic edema of the tongue, lips and eyelids and violent sneezing in 1) appeared, both patients subsequently tolerated thiamine hydrochloride orally without any untoward effects. Why this was so is hard to explain, possibly a rather high threshold of sensitivity to vitamin B₁ existed in these individuals and when it was taken

orally there may not have been a sufficiently high level at any one time to evoke an allergic reaction. The immunologic response of the patients was identical with that of well known sensitizing proteins. Constitutional reactions resulted only when the interval between injections exceeded one week. The possibility of an allergic reaction following paracutaneous administration increases as the interval between injections is lengthened. Intradermal tests were positive and passive transfer tests were negative. Five other similar cases have been reported.

Myasthenia Gravis—Constans and Radl present 11 cases of myasthenia gravis in which the prostigmine test was a valuable diagnostic aid. In 2 a relationship to pregnancy is brought out and in 2 cold or grip. The response of a particular patient to one form of therapy or even to a combination of different therapeutic agents varies. Before prostigmine is used orally or otherwise, myasthenia gravis must be known to be present. Patients must realize the type of affliction they have and must live within their limits of physical endurance. A few simple aids for the improvement and comfort of the patient while undergoing treatment are an eye patch for the relief of distressing diplopia, spectacles with a darkened or frosted lens or the painting of the lens on the affected side with clear nail polish. Prisms may be successful. Aminoacetic acid and ephedrine have been of definite value. However, less expensive medication, such as ephedrine sulfate and prostigmine bromide, has also been of value. Atropine may be needed to overcome some of the drying effects of the prostigmine. Prostigmine methylsulfate may be needed subcutaneously or intramuscularly if serious symptoms occur. Aminoacetic acid and ephedrine have been of definite value and should be tried. The dose of aminoacetic acid must be large. The dose of ephedrine sulfate will vary from $\frac{1}{8}$ to $\frac{3}{8}$ grain (0.008 to 0.024 Gm) two to three times a day. Like prostigmine, it is probably best to use small doses frequently.

Finger Sucking—On the basis of eight years of studying the dental aspects of 1,000 newborn infants, of more than two hundred models of their gum pads and a serial study of 50 children from birth to 5 years, which included from two to twenty sets of consecutive casts for each child, Sillman found that in all newborn infants the mandible is posterior to the maxilla, giving the chin the appearance of receding. From birth to 2 years the mandible grows forward faster than the maxilla. This contributes toward changing the features from those of a baby's face to those of a child's face. After 2 years this relationship of the jaws is generally maintained. Irregularities of the teeth are common in the first dentition, regardless of habit. Rotations of the incisors and molars are often present even before the teeth erupt. This point is extremely important to remember before finger sucking is said to be the cause of crooked teeth. Before and during eruption of the deciduous teeth, particularly the first incisors and first molars, the child's urge to bite is a physiologic process and usually passes unevent-

fully before the age of 3 years. During this time, heckling adults are apt to make suckers of nonsuckers or to accentuate the force of sucking and create a habit. Under such conditions displacement of the teeth will occur. A force of a certain intensity and duration will change the position of the teeth and the surrounding structures whether the force is applied with an orthodontic appliance or a finger, but one must be sure that such a force is operating. In any event the only area involved is the site of application, i. e. the anterior region. The force that maintains the mandible in its proper position is far greater than the force of the sucking. If by the age of 4 years the child persists in finger sucking, he should be helped to stop it. In instances in which sucking had caused crooked teeth, the displaced teeth corrected themselves spontaneously after the sucking was stopped.

Public Health Reports, Washington, D C

57 1559-1598 (Oct 16) 1942

- *Prevention and Treatment of Agranulocytosis and Leukopenia in Rats Given Sulfamylguanidine or Succinyl Sulfathiazole in Purified Diets S S Spicer F S Daft W H Sebrell and L L Asburn—p 1559
*Incidence of Cancer in San Francisco and Alameda Counties Calif 1938 H J Sommers—p 1566

Agranulocytosis and Leukopenia in Rats—The nutritional experiments on rats of Spicer and his co-workers with sulfaguanidine and sulfasuxidine (succinyl sulfathiazole) have demonstrated that agranulocytosis, leukopenia and hypocellularity of the bone marrow will develop in animals given either drug in a purified diet. However, most of this blood dyscrasia can be prevented or successfully treated with whole dried liver or with certain liver extracts.

Incidence of Cancer—The data obtained by Sommers from all physicians, hospitals and clinics in San Francisco and Alameda Counties, Calif., of all patients treated or observed for any malignant growth during 1938 show that of 7,859 patients 5,773 were residents and 2,086 nonresidents. There were 1,974 cancer deaths recorded, 173 of which were in resident cases not reported by doctors or hospitals. If these are added to the reported cases the total of resident cases is 5,946. The prevalence rate was 525.7 per hundred thousand residents. To a certain extent this high prevalence rate in the area is attributable to the unusually old population. The most frequent primary sites of cancer in males were the digestive tract, skin and buccal cavity, in women the breast, uterus and digestive tract. The cancer incidence per hundred thousand men was 416 and for women 611. The incidence rates for those first seen in the study year were 255 per hundred thousand men and 314 per hundred thousand women.

Irradiation of Cavernous Hemangioma—Kerr treated 96 cases of hemangioma with radium plaques at a distance of 2 mm and 49 with short distance contact roentgen therapy. Of the first series the results were good in 61, fair in 14 and poor

in 11, 10 were inadequately treated or followed. The respective figures for the other series are 34, 7, 3 and 5. The author thinks that not enough attention has been given roentgen therapy in the care of this condition. The slightly better results obtained with roentgen therapy are probably of no great significance, but when the apparatus is available its use is recommended.

Medical Examiner System in Rhode Island A. R. Moritz, Boston —p. 205

*Fluid Administration R. O. Bowman Providence —p. 207

Fluid Administration—Fluid or water therapy, Bowman points out, must like all medical treatment be on a sound physiologic basis or definite harm will result. In general the patient whose illness is not complicated needs at least 2,500 cc of fluid daily for water balance. If it must be given parenterally, 1,000 cc of this amount should consist of isotonic solution of sodium chloride and 1,500 cc of isotonic dextrose in water. If fever or profuse sweating is present the amount should be increased at least by another thousand cubic centimeters, preferably of the dextrose solution. After vomiting or gastric drainage the volume lost should be replaced by an equivalent amount of isotonic solution of sodium chloride. After diarrhea the volume excreted should be compensated by 1,000 or more cc of isotonic solution of sodium chloride or 500 cc of an alkaline solution and 500 cc of saline solution. Hypertonic solutions should be used to relieve cerebral or pulmonary edema. They have no place in the treatment of dehydration. Whole blood should be given only when extra erythrocytes and hemoglobin antibodies, platelets or fibrinogen are needed. For the prevention of shock sufficient concentrated plasma or plasma should be given to keep the hemoglobin or erythrocyte count from rising. If plasma is not available, hypertonic solutions of dextrose or sodium chloride are of some help, dextrose is better. Crystalloid solutions are of little value once shock has developed. Fluids may be given by mouth, rectum and clysis. More important than the decision to give fluids is the decision of what kind of fluid and how much to give.

Sulfonamides for Gonorrheal Conjunctivitis—Levy and Lewis treated 137 cases of gonococcal conjunctivitis with sulfonamides. Toxic reactions, with the exception of 1 early case, were practically negligible. Nausea was frequent, especially when sulfapyridine was administered. Slight cyanosis was common. Sulfapyridine and sulfathiazole are definitely superior to sulfanilamide in the treatment of gonococcal infections of the eye. Usually a cure may be expected within three days. Local treatment does not compare favorably with the internal use of the drugs. Every patient with gonococcal conjunctivitis should have immediate and adequate systemic treatment with sulfathiazole, and as an adjunct a 5 per cent sodium sulfathiazole solution should be instilled locally.

Carcinoma of Lung—Johnson and Daniel state that pneumonectomy is the patient's only chance for cure from lung cancer. Radiation therapy is only a palliative measure. The duration of the life of patients not operated on or treated with

radiation varies from a few weeks to about three years, during most of which time many are in distress. The operative mortality rate of pneumonectomy is about 30 per cent, this is not high when it is remembered that the disease is always fatal if pneumonectomy is not performed. Several cases in which carcinoma of the lung was cured for five or more years are cited. Success depends on the alertness of the medical profession in detecting the disease in its early stages.

Lecithovitelin Reaction and Gas Gangrene—Weed and his associates show that the reaction (opacity or a precipitate) of *Clostridium welchii* to normal human serum or lecithovitelin is not specific either for *C. welchii* or for its toxin. In their experiments the reaction was produced (undiminished) by the supernatant fluid from cultures of *C. welchii* after boiling for one hour—long after the lethal and the hemolytic factors were destroyed. The reaction may be prevented by monovalent anti-toxin for *Clostridium tetani* and *Clostridium septicum*, normal human serum and tenth molar phosphate buffer (pH 7) and by

adjusting the pH to 7.4 with normal sodium hydroxide. Cultures of *Cl. welchii* grown in Taylor and Stewart's casein medium, which does not permit production of type A toxin, give more rapid and definite lecithovitin reactions than those grown in chopped meat broth. Uninoculated casein broth will give a positive lecithovitin reaction when the pH is lowered sufficiently. The degree of acidity necessary varies somewhat with the particular batch of medium used. The reaction is obtained with a wide variety of aerobes which cannot possibly be confused culturally or serologically with *Cl. welchii*. The reaction produced by the common aerobes may be prevented by monovalent antitoxin for *Cl. welchii*, *Cl. tetani* or *Cl. septicum*. The reaction can also be inhibited by normal human serum and by tenth molar phosphate buffer (pH 7). Therefore the reaction cannot be relied on as a rapid diagnostic method for detecting the presence of *Cl. welchii* toxin or antitoxin.

Purulent Meningitis—The subjects of investigation by Feldman and his co-workers were 24 patients with meningococcic meningitis and 18 with purulent meningitis admitted during the past nine months to the isolation pavilion of the Gallinger Municipal Hospital and treated with sulfadiazine. Those with purulent meningitis were also given specific serum. The initial dose of the drug for adults consisted of 4 to 6 Gm., followed by 1 Gm. every four hours. Children were given half of an initial twenty-four hour dose and then daily approximately 1 grain per pound (0.14 Gm. per kilogram) of body weight. The drug was taken orally except by unconscious patients or patients who were vomiting severely. These were given the drug in the form of the sodium salt intravenously or subcutaneously. Treatment was terminated abruptly after the patient had been asymptomatic for about a week. The temperature of 18 of the 24 patients returned to and remained within normal limits within forty-eight hours after the first dose of sulfadiazine. Simultaneously with the fall of temperature the number of leukocytes decreased, the condition of the spinal fluid improved, the rash regressed rapidly and the patient generally improved. The temperature of 4 other patients who recovered came down more slowly, and improvement in general was more gradual. Twelve of the 24 patients were less than 2 or more than 30 years of age, the 2 who died were in the latter group, 1 a man of 44 and 1 a man of 53. Both were admitted in a severe state of acute alcoholic intoxication. The average level of sulfadiazine in the blood the day the temperature reached the base line and remained there was 82 mg. per hundred cubic centimeters, with a range between 37 and 176 mg. This refutes the idea that in patients with meningitis the blood level of a sulfonamide compound should be around 15 mg. Of 6 patients with influenzal meningitis 5 were infected with type B organisms. All were treated with sulfadiazine and homologous rabbit antiserum. Four who were more than 3 years of age made uneventful recoveries. The fifth patient, an infant of 7 months admitted with acute otitis media due to type B influenza bacillus, had been started on sulfapyridine prior to culture reports. The drug was continued, but in spite of adequate levels of the compound in the blood his condition became steadily worse and on the seventh day of therapy signs of meningitis developed. Treatment was begun with specific antiserum and sulfadiazine, but the patient did not rally. At necropsy there was evidence of petrositis on the same side as the otitis media observed on admission. The sixth of these patients was admitted with the diagnosis of a cerebrovascular accident on the basis of a history of a frontal headache for four days followed by hemiplegia. Lumbar puncture revealed purulent fluid containing numerous pleomorphic gram-negative bacilli. The diagnosis of meningitis and sinusitis was confirmed at necropsy. The experience with the 6 patients who had pneumococcic meningitis was as discouraging as it was encouraging in the two preceding groups. The pneumococcic meningitis of only 1 of the patients in this group was primary, but even she did not recover despite a slight improvement at the start of treatment. At necropsy a thick, adherent, basilar exudate was encountered, with no evidence of abscess or other foci of infection. On initial lumbar puncture 6 other patients with purulent meningitis had cell counts ranging from 600 to 3,200 per cubic millimeter, normal

reduction of Benedict's solution and no organisms on smear or culture. Five of these patients had presumably organic cardiac murmurs, and necropsy revealed bacterial endocarditis without gross evidence of meningitis. The sixth patient was admitted in a deep stupor and died fourteen hours later. Necropsy revealed a massive abscess involving almost the entire left temporal lobe, for which neither the cause nor the mechanism could be explained.

Clinical Fetal Electrocardiography—Goodyear and his co-workers used a standard portable amplifier type electrocardiograph in conjunction with a single stage resistance coupled preamplifier with abdominal leads to take 181 fetal electrocardiograms. The results were positive in 87 per cent. The electrocardiographic examinations were made on 154 gravid women pregnant for four or more months. The technic proved helpful in the clinical solution of a variety of obstetric problems and in detecting multiple pregnancy. The fetal heart rate and such factors as the duration of pregnancy, maternal heart rate or the sex of the fetus were not correlated. The amplitude of the fetal electrocardiogram bore no relation to maternal size or to the age and size of the embryo except practically at term, when the fetal deflections usually became larger. The electrocardiographic diagnosis of fetal position was fairly successful with the abdominal lead combinations employed but showed no advantage over usual clinical methods. The practical application of fetal electrocardiography is not primarily for the diagnosis of pregnancy, as the biologic tests answer this question earlier and with fewer false negative results, but rather in the ability of a positive electrocardiogram to reveal immediately that the fetus is alive when fetal movements and heart sounds are imperceptible. In this respect a positive electrocardiogram is more significant than a positive biologic test, as the latter depends on the presence of chorionic tissue and may remain positive for a week or two after the death of the fetus. The graphic method will detect multiple pregnancy earlier than roentgenography. Fetal electrocardiography has proved valuable in differentiating between cephalic, breech and perhaps transverse presentations. Unusual variations in the fetal heart rate or rhythm may suggest fetal abnormalities of distress and a fetal wave lasting longer than 0.04 second may indicate congenital intraventricular block. The effects of drugs, anoxia, toxemia, anesthesia and labor on the fetal heart action can probably be conveniently studied by this method. The detection of the action current of the fetal heart in utero during the second and third months of gestation would be important, as it is at this time that the problem of ectopic gestation is most troublesome. Such further development is largely a technical matter and offers a challenge to ingenuity.

Epidemic of Hepatitis—Evans reports the occurrence between October 1939 and June 1942 of 65 cases of epidemic hepatitis in a hospital among children and nurses. The hospital cared at one time for as many as 120 children and a variable number of adults. The infectious hepatitis became endemic in the hospital early in 1940 and the epidemic started the following winter. It gradually subsided in the next year and a half, but the frequent introduction of young nurses and children into the community is likely to maintain the infection and form a reservoir from which the disease can be distributed to other places. Infection is usually transmitted from case to case, but abortive cases are probably important links in the chain of infection. Young children and senior nurses were less susceptible than older children and junior nurses. The incubation period was usually about a month but shorter and considerably longer periods are possible. The duration of infectivity is uncertain. Several weeks of invalidism may often follow the infection. The blood sedimentation rate may remain elevated many weeks after a mild attack. Relapse and second attacks are uncommon but have been recorded. The mode of transmission in the epidemic, as in most, appeared to be arial and perhaps also by contagion. The frequency with which nurses became infected by nursing patients is striking when compared with the rarity with which patients in bed infected other patients and suggests the possibility of the acquisition of the virus from feces or urine. Usually a direct communication could be traced from case to case, at times an abortive case seemed to be the cause. Healthy carriers have been suggested as playing an active part.

Inpatient Treatment of Neurotic Casualties—Maclay and Whitty report the results of the first hundred patients (whose long continued neurosis made them unfit for work) who were treated in an emergency medical service neurosis center between July 1941 and January 1942. Their average age was 45, revealing that the stresses of war fall more heavily on older persons. All had been closely exposed to bombing, which resulted in some physical injury to 50. Severe mental stress, such as loss of husband, wife or children, loss of home or business or being buried for hours had been endured by 86. The average duration of incapacity for the 100 patients before admission was seven months. The factors responsible for the persistence of symptoms appeared to be fear of exposure to another severe experience in 39 instances, domestic and financial factors in 42, pension considerations in 13, the illness helping to solve a preexisting problem in a few, physical factors in 24 and physical illness in 11. The foregoing factors were rarely single. The most important symptoms were anxiety states in 37 instances, hysteria in 25, depression in 22, physical in 11 and schizophrenia in 2. 3 patients left before they were fully investigated. One third of the patients left the hospital by the end of a month, one half by two months and two thirds by three months. The best results were obtained by those who recovered

quickly. The results suggested that the patients had been awaiting specialized treatment such as can be rendered in a hospital and could not have recovered without it. Of the patients who showed no change, 2 suffered from schizophrenia and 5 from a physical illness which could not be expected to improve, thus only 12 were not benefited by the psychiatric treatment. In 57 the onset of the illness was wholly due to the precipitating incident and in another 18 it was due to the incident but there were previous predisposing personality characteristics which did not amount to a neurotic illness. The others were regarded as instances of neurotic relapse or aggravation of preexisting physical illness. The treatment adopted was that ordinarily used in psychiatric practice: persuasion, explanation, reeducation, removal of symptoms by suggestion and occupational and physical therapy. The important feature was an assessment of the factors responsible for the persistence of the illness and their removal whenever practicable. Practical difficulties allowed only 36 patients to be followed up. This revealed that after an interval of six months the estimated prognosis of 26 corresponded to that at discharge, of 5 it was better and of 5 not as good. Specialized inpatient treatment of neurotic casualties appears to be well justified by the results.

New Remedy for Scabies—Perceval used tetraethylthiuram monosulfide for treating 50 patients with scabies. It was non-irritant when applied as a pure powder and cutaneous idiosyncrasy was not encountered. It was curative in a 5 per cent liquid preparation, 25 per cent tetraethylthiuram monosulfide, 10 per cent of polyglycerol ricinoleate and 65 per cent of industrial methylated spirit. One part of this oil was added to four parts of water immediately before use. The 25 per cent concentration remained stable at room temperature but crystallized at a lower temperature. Gentle heating redissolved the crystals. The diluted oil separates and thus the required 5 per cent dilution should be prepared just before use. For cure the preparation was rubbed over the whole body, with the exception of the head, face and neck, twice a day for three days.

Proflavine Powder in Wound Therapy—Proflavine powder was tried by Mitchell and Buttle in the treatment of eighty wounds that proved intractable to chemotherapy. Experimental work has shown that the substance was relatively non-toxic and had a strong bactericidal effect on many organisms. Various forms of treatment, apart from routine sulfonamide therapy and closed plaster, were tried in the 80 resistant cases. Failure of the methods led to the dusting of proflavine sulfate powder into the wounds. The amount of proflavine used never exceeded 2 Gm, and usually only about 0.5 Gm or less was employed. This depended on the size of the lesion. It was introduced into cavities by a small Volkmann's scoop or the end of a blunt dissector, or in extensive wounds it was dusted over the entire surface and evenly distributed with a spatula or scalpel handle. It was never employed more than two or three times, four to twenty-eight days elapsed after each appli-

cation When used prophylactically the amount varied according to the size of the lesion but was usually about 0.25 Gm mixed with 2 to 5 Gm of powdered sulfanilamide. The use of the proflavine has resulted in beneficial results in almost every instance. When staphylococci were the infecting organisms, proflavine has proved more efficient in controlling or eliminating the infection than any other drug so far tried, and the response of many wounds with mixed infections has also been good. With one exception there has been no interference with healing. The dressings were usually painless, and no general toxic manifestations have been observed.

Nicotinic Acid and Angina Pectoris—Neuwahl treated 6 patients suffering from angina pectoris with niacin and the results appear to be remarkably uniform and lasting. Oral administration of the drug caused a noticeable decrease in the number and the severity of attacks in several patients, in others the effect was transient, possibly because absorption or interaction of chemical substances in the gastric secretion was interfered with. Intravenous administration heightened the efficacy of the drug. Therefore to obtain equal conditions oral administration was discontinued and a drip infusion of a 0.05 per cent solution of niacin was chosen to overcome differences in susceptibility. One infusion of 100 to 300 mg of niacin produced as a rule a remarkably beneficial result, which was maximal after twelve to twenty-four hours. Further infusion seemed to cause a definite stabilization in the condition of the patients, who became free from anginal attacks after several weeks. The worst affected patients reacted best. Usually six infusions were sufficient. The symptoms of the 6 patients have completely or almost completely regressed for three to seven months after the course of treatment was completed, 3 have actually resumed heavy manual work.

Drug Fever and Chills Due to Sulfathiazole—Moeschlin reports 6 patients who developed drug fever in connection with sulfathiazole medication. Tolerance tests demonstrated that the fever was the result of specific sensitization. This sensitization, however, did not apply to other sulfonamide derivatives. Patients who have become sensitized to sulfathiazole may react with decided chills to the renewed administration of even small doses of the drug. These chills, together with high temperatures, increased leukocyte count and accelerated blood sedimentation may simulate septic conditions. Absence of granulations in the neutrophils indicates drug fever in cases in which the diagnosis is doubtful. In cases in which drug fever is suspected, the sulfanilamide preparation should be discontinued or should be replaced by another of the sulfa drugs, because a patient sensitized to one of these compounds may tolerate others. By ascertaining the sulfa content of the blood, it could be demonstrated that rise in temperature appears a short time after the offensive compound enters the blood stream. Drug fever produced by sulfathiazole is sometimes accompanied by corneal infiltration, marginal phlyctenae and glossitis, but these are of short duration. Existence of a drug fever should be investigated, when, in the course of treatment with sulfa drugs, no reduction in temperature is effected in the course of a few days.

Clinical Significance of Arcus Lipoides (Arcus Senilis) Corneae—Question has been raised whether the presence of a lipid ring in the cornea suggests the existence of similar pathologic processes in other parts of the body. It has been suggested that arcus senilis of the cornea makes arteriosclerosis probable. Rintelen investigated the problem on a large necropsy material. The eyes of 600 comparatively fresh cadavers were inspected without optic aids for the presence of the senile arcus. A noticeable lipid ring was detected in 214 cases. Examination

of the entire vascular system of the 214 cadavers disclosed that 66 (31 per cent) had no signs of arteriosclerosis, 97 (45 per cent) had a moderate sclerosis of the entire or of a part of the arterial vascular system, only 51 (24 per cent) had a severe sclerosis, particularly in the large vessels. No lipid ring was seen in 39 of those who had reached an age of more than 60 years, but 13 (33 per cent) had a severe arteriosclerosis, which in 7 had been the actual cause of death. The lipid ring was found 4 times in persons under 50 and none of these had arteriosclerosis. There is apparently no evidence of a close relationship between lipid infiltration of the cornea and arteriosclerosis. This is not surprising, when it is considered that the lipid ring of the cornea is an aging phenomenon with usually dominant hereditary transmission, whereas arteriosclerosis is an extraordinarily complex pathologic process.

Oncotic Pressure in Pathogenesis of Edema—Juncadella Ferrer studied the relation between oncotic pressure and edema; the levels of oncotic pressure which by themselves can be regarded as causing edema and the involvement of the alteration of the oncotic pressure in edemas observed in different syndromes and diseases. The protein formula and the oncotic pressure were determined in 401 cases in 136 of which edema existed at the time of determination. Numerous examinations were made on the edema fluid and on the blood volume. Clinical studies demonstrated that a definite connection exists between oncotic pressure and edema. The edema increases proportionately to the decrease in pressure. At a pressure below 15 cm of water edema is a necessary result, and it is frequent when the pressure is below 25 cm. In such cases the decrease in pressure alone suffices to explain the edema. At pressures above this level edema becomes consistently rarer and other eliciting and contributing factors must be searched for. Oncotic pressure values above 40 cm of water are normal, so that if edema develops with such pressures other factors are responsible. In secondary anemia edema is encountered in the presence of normal or only slightly reduced oncotic pressure values. In the edemas of leukemia the oncotic pressure factor likewise plays an unimportant part. In the edemas of cardiac patients the oncotic pressure plays a variable role, it is apparently not the primary causal factor but an important additional factor. Acute glomerular nephritis is accompanied by high oncotic pressure, and the edemas developing cannot be ascribed to it. In pernicious anemia the oncotic pressure seems to play an auxiliary rather than a primary role in the development of edema. The edemas of chronic glomerular nephritis exist in the presence of widely varying oncotic pressures. In serum disease edema develops in the presence of extremely low oncotic pressure values, that is, in these cases edema is obligatory. During nephrosis and amyloidosis the edemas are characterized by a low oncotic pressure.

Asthma from Sensitization by Bedbugs—Lahoz and Recatero describe 4 cases of asthma which they could trace to sensitization by bedbugs. Three of the 4 patients had seasonal asthma, and the possibility of sensitization by pollen was considered. All 3 improved when they changed their residence. The improvement when living in homes not infested with bedbugs and still more the experience in the open air make the authors reject sensitization to pollen. This was further confirmed by negative skin reactions to pollens. Sensitization to spores of *Tilletia* could also be ruled out by negative skin reactions. Routine intradermal tests gave slightly positive reactions to bacterial substances and completely negative reactions to fungi, pollens, house dust, wool, feathers, hair and the like. Tests made with extracts of bedbugs gave strongly posi-

tive reactions whereas the same extracts were negative in persons with other forms of allergy and in healthy persons. The patients were advised to remove the bugs from their homes by thorough cleaning, repainting and, if possible, change of furnishings. Treatment consisted in progressively increasing injections of extract of *cimex lectularius*. Two of the 3 patients passed the summer of 1941 without attacks, and in the third an equally favorable result is hoped for, although the injection of the maximal dose elicited a severe local reaction and an attack of asthma. A secondary sensitization of the fourth patient to bedbugs could be demonstrated. The authors consider that the odor, the bite or the contact with the insect or its excretions may be responsible.

Beitrage zur klinischen Chirurgie, Berlin

Traumatic Cholecystitis—Biehl observed 3 cases of biliary disorders which had occurred in connection with trauma. A railroad worker aged 22 was thrown against a crank the impact striking the epigastric region. He experienced immediately a severe pain in the gastric region which was intensified on movement and on deep breathing. The pain radiated toward the right scapula. The patient later collapsed and was brought to the hospital. Laparotomy disclosed that the gallbladder was torn away from the liver bed. The bladder was removed. The second patient was a man aged 54 who had fallen from a bicycle. At operation two days later there was found peritonitis caused by tears in the small intestine. An intestinal resection was performed. Three weeks later the patient was subjected to a cholecystectomy because of symptoms of acute cholecystitis. The removed gallbladder presented a circumscribed mucosal tear in the fundus of the gallbladder. The wall in the region of the tear was necrotic but perforation did not take place. Colon bacilli apparently had entered the gallbladder and had caused a cholecystitis. The third patient was a man aged 52 who had been in an automobile accident and had sustained a patellar fracture. Suture of the patella was followed by suppuration of the knee. The patient was not aware of having sustained an abdominal trauma, but five weeks after the accident there suddenly developed an acute cholecystitis which necessitated a cholecystectomy. The gallbladder contained 2 calculi. The thickened wall in the region of the corpus was found to contain numerous intramural abscesses. In the region of the fundus there was an inflamed mucosal flap, and a portion of the wall was denuded of mucosa. It is suggested that streptococci which produced the mural abscesses had found a breeding place under the torn off mucosal flap and that the postoperative suppuration of the knee was probably a hematogenous result of the cholecystitis. The mucosal lesions in cases 2 and 3 were probably caused by trauma. The resulting cholecystitis therefore may be designated as "traumatic cholecystitis."

Fragility of Blood Vessels in Internal Diseases—Schaefer investigated the incidence of the impairment of the vascular wall in internal diseases, using the vascular fragility test of Sack. A certain negative pressure is exerted by means

of a suction cup on the small cutaneous vessels until vascular tears appear. The author reports observations on 97 persons, of whom 14 were healthy. The vitamin C content was determined in order to rule out its influence on vascular fragility. It was found that in the majority of the cases there was a vitamin C deficiency. Only in 10 out of 97 there was no vitamin C deficiency. The patients were given daily a certain quantity of vitamin C until 50 per cent of it was eliminated in the urine. This is regarded as an indication of saturation. The vascular fragility test of Sack was employed before and after saturation with vitamin C. The test is suitable for the quantitative determination of vascular fragility. An increase in vascular fragility is observed in infections and inflammatory diseases, in diseases of the vascular system and in case of toxic impairment of the vascular wall by arsenic. There is no impairment of the vascular wall in leukemia, anemia and polyglobulism.

Counting of Thrombocytes—The fact that no less than sixty-one methods have been described suggests the inadequacy of the individual methods. Meister investigated methods which are fundamentally new, have been evaluated favorably and meet clinical requirements. The various methods employ cutaneous blood, venous blood, the plasma counting chamber, the whole blood counting chamber, with or without hemolysis and a streak or a smear preparation. She found that the same figures are obtained regardless of whether cutaneous or venous blood is used. Methods which utilize plasma are unsuitable because the thrombocytes are unevenly increased in the plasma, whereas fewer are carried along in the sedimentation of the erythrocytes. If the whole blood counting chamber is used with hemolysis, the visual field is filled with numerous point and threadlike fragments of the hemolyzed erythrocytes, which makes differentiation of platelets impossible. If the whole blood counting chamber is used without hemolysis, a part of the platelets are destroyed by the fixation fluid. The count is dependent to a considerable extent on the degree of hemolysis. She concludes that the streak preparation of Papanicolaou or the ordinary blood smear (according to Sack's suggestion) yields results correct within the margin of error.

Pulmonary Embolism—Hachmeister raises the question as to the cause of death in pulmonary embolism. Clinical observations on pulmonary embolism being difficult, because the fatal cases terminate rapidly and the mild cases are rarely recognized, animal experiments were resorted to. Of the methods used heretofore only the intravenous injection of air can be regarded as physiologically unobjectionable. The author developed a method which closely imitates the physiologic conditions of human embolism. He injected emboli prepared from the animal's own blood. He was interested in investigating the quantity of emboli that can be injected at once without changes taking place in the arterial and venous blood pressure, the quantity of emboli that causes only temporary circulatory disturbances and the quantity of emboli which, injected at once, causes death. In the course of experiments on dogs the arterial blood pressure was measured in the left femoral artery and venous blood pressure in the left jugular vein. The emboli were injected into the right femoral vein. It was found that the injection of from two to five emboli produces no changes. The length of the individual embolus was 2.3 cm and the diameter 4.5 mm. Dogs of from 11 to 15 Kg in weight exhibited a fall in arterial blood pressure in response to the injection of from fifteen to twenty emboli. This change in arterial pressure appeared from ten to fifteen seconds after the injection of the emboli. The venous blood pressure increased after twelve seconds but attained its normal value in the course of approximately 27 minutes. The injection of from thirty to thirty-five emboli caused death in dogs weighing from 10 to 15 Kg. The severity of the symptoms of pulmonary embolism is to a great extent dependent on the number of individual emboli which invade the circulation, as well as on the time intervals at which the emboli follow one another. Embolism may result fatally even in the presence of adequate possibilities for the pulmonary circulation. The question whether other, perhaps reflex, factors play a part and cause a further shutting off of pulmonary arteries and thereby death was not explained by these experiments.

Book Notices

Aftereffects of Brain Injuries in War Their Evaluation and Treatment The Application of Psychologic Methods in the Clinic By Kurt Goldstein M.D. Clinical Professor of Neurology Tufts Medical School Boston Foreword by D. Denny Brown M.D. Professor of Neurology Harvard Medical School Boston Cloth Price \$4 Pp 244 with 49 illustrations New York Crane & Stratton 1942

During the war of 1914-1918 Kurt Goldstein, the author of the present volume, probably had more experience in studying head injury cases from a neurologic point of view than any other person on either side. Goldstein, a competent observer, prolific writer and excellent neurologist, has produced this small volume comprehensively covering the neurologic symptoms and sequelae of head injuries and their origin from a neurologic-mechanical point of view. In addition he discusses some extensive psychologic laboratory studies of these cases, the tests being primarily psychophysical in type. This chapter is interesting because it shows the practical nature of the tachistoscope, the ergograph and other little used but easily applicable quantitative instrument tests of coordination. The book closes with two chapters which will be widely read by physicians who have to do with the rehabilitation of head injury cases. These chapters deal with the treatment by physical and neurologic means and the social adjustment of these head injured. There is an extensive and useful bibliography appended to this volume. The work is modern, practical and useful and is the first book of its kind to be made available for the wounded of the present conflict. While the material will be amplified by future studies, the soundness of the contents will make this book a must for therapists with post-traumatic neurologic patients.

Introduction to Parasitology By A. S. Pearse Professor of Zoology Duke University Durham N.C. Cloth Price \$3.75 Pp 357 with 448 illustrations Springfield Illinois & Baltimore Charles C. Thomas 1942

In the brief confines of this book the author has surveyed the field of parasitology from protozoa to bats. The book is intended as a reference work for college students to be used in conjunction with lectures and laboratory work. Emphasis is placed on parasites that infest man, however, and whole chapters are devoted to malaria and hookworm. The medical technologist will find detailed instructions for many procedures of laboratory diagnosis. At the end of some of the chapters is a brief paragraph outlining medical treatment. On the whole these are satisfactory for the purpose intended, although there are a few instances in which a proprietary preparation has been mentioned, such as stovarsol for ciliate infestations instead of the chemical name acetarsone. The final chapter is devoted to instructions for the collection and care of parasites for laboratory collections. The book is recommended for persons desiring a synopsis of parasitology.

Internal Secretion of the Germinal Tissue of the Testes and Prostatic Hypertrophy By Nils Tornblom Published in Uppsala Lakareforenings forhandlingar Ny foljd Bd XLVIII 12 Paper Pp 106 with 68 illustrations Uppsala Almqvist & Wiksells Boktryckeri AB 1942

The author discusses the etiology of prostatic hypertrophy as related to the question of (1) more than one hormone formation in the testis, (2) an independent endocrine function of the germinal tissue of the testis, (3) an increased formation of testosterone after cessation of internal secretion in the germinal tissue, (4) isolation and characterization of hormone formed in germinal tissue of the testis and (5) induced changes in the prostate by increased action of testosterone, similar to spontaneous prostatic hypertrophy. Tornblom shows by experimental studies on rats and dogs that two hormones are formed in the testicles, one in the germinal tissue and one in the interstitial cells. The latter hormone (testosterone) stimulates the growth of the prostate and seminal vesicles. The germinal tissue hormone is characterized in relation to testosterone by a greater weight increase of the hypophysis in castrated rats than in the growth of the prostate and seminal vesicles. Cessation

of the internal secretion of the germinal tissue in rats produces increased weight of the hypophysis as well as an increased production of testosterone in the interstitial cells which stimulates the growth of the prostate and the seminal vesicles. The author points out that the hormone of the germinal tissue has been isolated, and when administered in small doses to castrated rats it inhibits the weight increase of the hypophysis. The increased action of testosterone (testosterone propionate) produces enlargement of the prostate in dogs which is similar histologically to the hypertrophy of the prostate usually encountered.

Castor Oil and Quinine Once a Doctor Always a Doctor By George Wonsow Vandegrift M.D. Cloth Price \$3 Pp 232 New York E. P. Dutton & Co. Inc. 1942

The son of an eccentric, masterful and lovable physician has written this very human book about the "Corner Doctor" in New York's old seventh ward in the colorful eighties and nineties, which closed the nineteenth century. Dr. Vandegrift Sr. had an intuitive diagnostic ability and a hypnotic influence over his patients, especially the females, and an unusual amount of common sense, curiosity and energy. With an extraordinary gift for making friends, he hobnobbed with every one from burglars to some of the most famous litterateurs of his day. His medical practice overflowed the office in his home at all hours, and many of his patients had such confidence that they either followed him on his vacations to his farm in Maryland or would often cause him to terminate these short periods by constantly wiring or writing for his quick return to New York. He wore a high hat, opal studs, a long coat and yellow linen duster. He dined late and got about late. His patients waited by the hour in the office until he was ready to see them and always seemed well rewarded even though they were subjected to nauseating shotgun prescriptions or his favorite shorter prescription of castor oil and quinine. The son, and the author became a physician and took over his father's practice, however slow at first, as many of the patients refused to see any one but his father. His story, warm with humanity, humor and vitality, contains vivid pictures of his father and old New York. Indeed, if the late Charles Dickens, the great Englishman, had known father Vandegrift, we would probably have had another work as famous as "Dombey and Son."

The First Negro Medical Society A History of the Medico-Chirurgical Society of the District of Columbia 1884-1939 By W. Montague Cobb A.B. M.D. Ph.D. Associate Professor of Anatomy Howard University Washington D.C. Cloth Pp 159 Washington D.C. Associated Publishers 1939

The Medico-Chirurgical Society of the District of Columbia is the oldest American Negro medical society. This small volume is a review of the difficulties in earlier days that Negro physicians encountered in becoming members of the Medical Society of the District of Columbia, which appears to be, the author says, the first scientific society chartered by act of Congress. This problem of Negro physicians back about 1870 finally reached the House of Delegates of the American Medical Association, and here are republished some of the reports of the committees to which certain phases of the problem were referred. The archives of the Medico-Chirurgical Society previous to 1920 could not be found by the author. For the last eighteen years there is a definite record of the programs of the meetings of the society, of which 58.6 per cent have been devoted to scientific discussions and the remaining 41.4 per cent to business the nature of which the author says was not always of sufficient significance to warrant the time spent on it. To this fact may be charged much of the lack of interest among the members of which the society has regularly complained. Of the eighty-five scientific meetings held in this period of years, in 43.5 per cent the programs were presented by visiting speakers. There are now 170 Negro physicians practicing or teaching medicine in the District of Columbia, of whom 84.7 per cent are members of the Medico-Chirurgical Society. The Negro population of

the District is said to be 170,000, making a ratio of 1 Negro physician to 1,000 Negro inhabitants.

The author lists some two hundred and nineteen publications by members of the society and briefly reviews the work it has done on community problems. The author points out some deficiencies of the society, yet he believes it has contributed to Negro medical progress in Washington.

The Problem of Cooperative Medicine By V. J. Tereshchenko. Studies of the Cooperative Project. Series B. Studies in the Field of Cooperative Medicine. Part I. Federal Works Agency Work Projects Administration for the City of New York. Published with the Assistance of the Edward A. Filene Good Will Fund, Inc. New York: Paper. Pp. 80. New York, 1942.

This work, which is "sponsored by the U. S. Bureau of Labor Statistics" and "published with the assistance of the Edward A. Filene Good Will Fund, Inc.," is made up largely of quotations from the carefully selected speakers of the National Health Conference, radio speeches and hostile critics of organized medicine on the one side, to which are contrasted quotations from articles and addresses of physicians who oppose the position of the first list of speakers. This is the old method of setting up straw men in which the verdict is decided in advance. It is admitted that "the concept of cooperative medicine has not become crystallized as yet and, therefore, causes confusion in the terminology now applied." The "well defined principles" of cooperation are stated, but there is no attempt to show that these principles are offered in the so-called cooperative health associations described. The opponents of cooperative medicine are said to maintain that "the whole problem of medical care can be solved simply by increasing the efficiency of the already existing system of medical care." Of course, no attention is paid to the fact that organized medicine has been conducting more plans to determine the best method for paying for medical care than all the "cooperative associations" combined.

Gregg Medical Shorthand Manual By E. M. B. Smither. Second edition. Cloth. Price \$2. Pp. 191. New York: Gregg Publishing Company, 1942.

The medical stenographer who uses Gregg shorthand will find this manual of great aid in the simplification of outlines for medical terms. Shortened forms for commonly occurring medical words, prefixes, suffixes and common phrases and word combinations with ample practice material are included. The introduction includes a list of Greek and Latin prefixes and suffixes with definitions, and various other practical hints for the beginner whose chief difficulty is lack of medical vocabulary. Emphasis is placed on the value of a knowledge of etymology, which, as any experienced reporter will confirm, is half the battle in devising outlines for unfamiliar terms in any branch of science and in any system of shorthand.

Medical Parasitology By James T. Culbertson, Assistant Professor of Bacteriology, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price \$4.25. Pp. 285 with 37 illustrations. New York: Columbia University Press; London: Oxford University Press, 1942.

This book consists of two parts, general considerations and infections caused by animal parasites. The first contains chapters on infection, epidemiology, natural resistance and acquired immunity, diagnosis, specific therapy and prophylaxis. Part II deals with the thirteen zoological groups of animal parasites. It is an uncritical compilation of data without citation of sources. Thus it is stated that "most adults are probably relatively resistant to *Endameba histolytica*. Among those who contract the infection, few manifest severe symptoms." This may be true at the time of detection in carriers or chronic cases but did not apply in the Chicago outbreak. The statement that the iron alum hematoxylin technic for detection of amebic cysts in stools is not often resorted to because of its difficulty is to be deplored, since it alone suffices to protect the patient from inadequate and all too often false diagnosis. The plates are based on photographs and contain some new material. The text figures are often quite inferior.

First Aid to the Injured and Sick. An Advanced Ambulance Handbook By Francis James Warwick and A. C. Tunstall. Edited by Norman J. Hammer, M.B.C.S., County Surgeon, St. John Ambulance Brigade, London. Eighteenth edition. Boards. Price \$2. Pp. 336 with 313 illustrations. Baltimore: William Wood & Company, 1941.

This handbook on first aid was brought out in England and has been well known there since its first publication in 1901. It is divided into two parts, the first dealing with the form and functions of the body—admirably brief and suitably illustrated—and the second with first aid. The latter, according to the preface, has been practically rewritten in the light of the reviser's special interest in air raid first aid. The sections on wounds from war weapons, war gases from the first aid point of view and the collection and immediate care of air raid casualties, including those affected or contaminated by gas, are especially noteworthy. The book is of handy pocket size and is suitably indexed. It is one of the best and most reliable books in the field.

Housekeeping Service for Chronic Patients. An Analysis of a Service for the Chronically Sick and the Infirm Aged Operated by the Work Projects Administration By Mirra Frenkel, M.D. Research Bureau, Welfare Council of New York City. Paper. Pp. 143. New York: Welfare Council of New York City, 1942.

The Welfare Council of New York City supervised a WPA project to provide housekeeping aides in the home care of chronic patients without expense to the patients. From Oct. 1, 1939 to June 30, 1940 such assistance was given for various periods to 2,508 patients, a majority of whom were over 65 years old and suffering from some form of disability which rendered them unable to do their daily household work, two thirds being confined to their homes. About one third required care throughout the year but the remainder for shorter periods. All were under medical supervision, but many did not demand active medical care. There was an extensive system of supervision, mostly by medical social workers which must have added greatly to the overhead expense. Unfortunately there are no figures given as to the total cost. Economic changes and the dissolution of the Work Projects Administration has now ended many features of this experiment.

Eat What You Want! A Sensible Guide to Good Health Through Good Eating By W. W. Bauer, M.D., Director, Bureau of Health Education, American Medical Association, Chicago, and Florence Maryne Bauer. With an introduction by Morris Fishbein, M.D. Cloth. Price \$2. Pp. 263. New York: Greenberg Publisher, Inc., 1942.

This is an unusually readable book on diet containing thoroughly sound information packed without appearing crowded, into a comparatively small number of pages. There are a number of tables including one on food values and another on the number of calories used per hour under various types of activity. There is a satisfying chapter on vitamins. The book explodes many dietary superstitions and advertising baloney. A number of retural menus either for home or for restaurant choice are included. All these features and others make this book especially useful for the reader who is not particularly trained in nutrition. The final chapter, "If you carry your lunch," seems especially timely.

First Aid and Bandaging. A Handbook of First Aid and Bandaging By Arthur D. Bellillo, M.B., B.S., D.P.H. and others. Cloth. Price \$1.75. Pp. 628 with 239 illustrations. Baltimore: William Wood & Company, 1942.

This is the fourth reprinting of this manual on first aid since May 1941, a record which speaks for the timeliness of the subject as well as for the quality of the contents. The arrangement is conventional, beginning with chapters on the general principles of first aid, case taking, diagnosis and the structure of the human body. The latter, although supplemented in later chapters by further description and illustrations, seems rather too abbreviated. There is more emphasis on bandaging in this book than in some of its contemporaries. The final chapter is devoted to training in first aid—a sort of outline of a first aid course. There is an adequate index.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

CAN HAIR TURN WHITE OVER NIGHT?

To the Editor—Can hair actually turn white over night or is this pure myth? What chemical imparts color to hair, I mean natural color not artificial? Can particle of pigment in a hair shaft be seen with the high power of the microscope in cross section or does it require a higher power than even oil immersion of the ordinary laboratory microscope?

M D California

To the Editor—One of our local high school boys had an argument with his teacher. The teacher claimed that it is quite possible for a person's hair to turn gray in a single night. I told the young man that in my opinion a person's hair could not possibly turn gray in one night but that I would go to the fountain head of all wisdom.

M D, California

ANSWER—The color of hair is due to pigment in two forms, a soluble one which pervades all the cells and also as fine granules which are most numerous in the outer part of the cortex but are present also in the central cortex and the medulla. The pigment is melanin, thought to be formed by the action of tyrosinase on tyrosin (Rothman, Stephen. In Vitro Studies on Pigmentation, *J Invest Dermat* 5 61 [April] 1942) and may vary widely in its color. Rothman, by exposing it in vitro to the action of ultraviolet radiation, caused it to become paler, a portion even losing all its color and becoming soluble. The melanin of blond hair is of a much different shade than that of red or dark hair. The amount of granular melanin varies a great deal, much more being present in dark hair. It may be seen by use of any of the objective lenses of the microscope. For the detection of gas in the hair the low power objective is best, for it allows more chance for light to strike the hair from above and be reflected. Too strong a reflected light is confusing for it lights up the many small reflecting surfaces mentioned by Strong (R M. The Cause of Whiteness of Hair and Feathers, *Science* 54 356, 1921) too brightly. A mild light will show the reflection from the gas without this confusion.

Occasionally in examining hairs by transmitted light, larger homogeneous dark masses are seen, which by reflected light appear white. These are globules of gas, to which further reference will be made. Besides reflecting globules of gas there are many minute breaks and angular surfaces in and on the hair, all of which reflect light and modify the effect of the melanin on the color of the hair. Jarnecke (H. Changes of Color of Hair by External Influences, *Dermat Wchnschr* 106 212, 1938) says that the content of silicic acid in hair also influences its color.

There are three theories of the way in which hair becomes gray.

1 The dark hair falls out and the new hair appears without pigment. This is a common occurrence in cases of alopecia areata. In younger patients the new hair acquires pigment after a time. In old patients it is apt to remain white. Most authorities agree that this is the way in which ordinary grayness occurs.

2 The cells of the medulla become phagocytic and carry off the pigment through the hair root (the theory to explain sudden blanching advanced by Metchnikoff, Elie. On the Process of Hair Turning White, *Proc Roy Soc London B* 69 156, 1901-1902).

3 The sudden blanching occurs by the formation of gas which appears in the hair, and the light reflex from these bubbles conceals the pigment, which remains in the hair.

The Metchnikoff theory was evidently an extension of his general theory of phagocytosis and has found no support.

The third theory found its greatest exponent in Landois (L. Die plötzliche Ergrauen der Haupthaare, *Virchows Arch f path Anat* 35 575, 1866) and is generally accredited to him, although he states that Griffith was the first to demonstrate the reflecting bubbles of gas in the hair. Landois supported his claim by microscopic study of the sudden blanching of the hair of a man aged 34 with delirium tremens, who originally had blond hair and blue eyes. Landois's theory is that hair suddenly blanched does not lose its pigment but the pigment is concealed by the reflexes from the gas bubbles. He agrees that ordinary gray hair, on the contrary, is usually gray because of loss of pigment.

The founders of modern dermatology in Vienna von Hebra and Kaposi, denied the possibility of the occurrence of sudden

blanching. Stueda (L. Ist plötzliches Ergrauen des Haupthaars möglich? *Deutsche med Wchnschr* 36 1484, 1910) wrote a paper denying it. Bloch (Bruno. Ueber die Entwicklung des Haut und Haarpigmenter beim Menschlichen Embryo und über das Erloschen der pigmentbildung im ergrauenden Haar [Ursache der Canities] *Arch f Dermat u Syph* 135 77, 1921) the discoverer of the dopa theory of melanin formation, disbelieved it. Galewsky, one of the greatest authorities on hair and hair diseases, was skeptical, and more recently, this same attitude has been voiced by Strong. The Suttons (Diseases of the Skin, ed 10, St Louis C V Mosby Company, 1939, p 1397) consider this possible. Most English speaking dermatologists accept the possibility of occasional cases of sudden blanching of the hair.

Strong's adverse opinion is founded on microscopic study of the hair. He found no more gas in gray hair than in pigmented hair, but the gray hair was deficient in pigment. For ordinary gray hair all authorities agree that this is true. Landois's claim was that suddenly blanched hair differed from ordinary gray hair in retaining its pigment, which is concealed by abundant globules of gas.

In the rare condition known as pili annulati, ringed hair, the white segments are white not because of loss of pigment but because of bubbles of gas that conceal the pigment. It is mentioned by H R Crocker in the second edition of his textbook (Diseases of the Skin, Philadelphia F Blakiston Son & Co 1893, p 790). Heepke (H. Ueber Veränderungen des Pigmentes und Luftgehaltes im Haar *Verhandl d Anat Ger* 30 127, 1931) studied a case of this kind. He found the gas difficult to remove, in contrast to Landois's experience. Cady and Trotter (A Study of Ringed Hair *Arch Dermat & Syph* 6 301 [Sept.] 1922) found that in most cases the gas was more or less resistant to removal, but 1 of their cases gave up the gas quite readily. They warn that such hairs should be examined soon after they are mounted lest they lose the gas. This is in accordance with Landois's experience. Further, their chemical experiments led them to suggest that the gas imprisoned in the hairs may be carbon dioxide.

Thus we have plenty of proof that gas bubbles can hide the pigment and cause still pigmented hair to appear gray. The statement that such gas can form and occupy a whole long hair in a few hours depends for proof on Landois's study, supported by a few others.

One of them, Heinicke (Zur Casuistik des Verhaltens der Haare bei Geisteskranken *Neurol Centralbl* 22 146 1903) relates the history of a woman aged 21 with dementia precox who during her stay in the hospital had several recurrences of her mental disturbance. It was noticed during one of these attacks that a strand 3 cm wide of her originally blond hair had become almost silvery white. It extended from the center frontal region to the left parietal region. After four days it rapidly resumed its normal blond color. The mental attack subsided soon after this. Three days later the same strand of hair became white and in an hour or two another mental disturbance set in. The hair strand at the height of this attack was again almost silvery but, as the patient improved had by the following evening resumed almost the normal blond color. Examination of these white hairs showed more air than in normal hair. This escaped by immersion in water and the hair regained its normal color. The change in color was accompanied by hyperalgesia of the part of the scalp from which this strand of hair grew.

It is difficult to doubt the accuracy of the observations of an eminent clinician such as Gowers (Metallic Poisoning, *Lancet* 2 1173, 1901), who in a lecture digressed from a discussion on arsenical pigmentation to relate a case of traumatic meningeal hemorrhage over the left cerebral hemisphere. During the three days that the man lived after the accident the right half of his brown moustache and beard became almost white, and in the median line, separating this gray hair from the brown hair on the left side, was a line of almost black hair. Gowers compared this to the tendency so often seen in depigmentation such as occurs in leukoplakia for the border of the light area to be hyperpigmented. This change was carefully watched during life and checked after death.

Brown-Sequard (Experience demonstrant que les poils peuvent passer rapidement du noir au blanc chez l'homme, *Arch de physiol* 1869, p 442), after remarking that many of the reports of sudden blanching of the hair are unreliable relates his own experience. In August 1862 he noticed a few white hairs in the beard on the anterior part of both of his cheeks where he had none before, though they had been present farther back on his cheeks. These new white hairs he pulled out, five on one side and seven on the other. Two days later he found three white hairs, white throughout their whole length on the right side and two on the left. These he also

epilated and repeated the process many times in the next five or six weeks. He was certain that pigmented hair became white throughout its length over night.

Sustantiating Brown-Sequard's observations are the conclusions of Naegeli (Beobachtungen beim Ergrauen der Haare im Hinblick auf die zurzeit herrschenden theoretischen Anschauungen, *Schweiz Med Wchnschr* 63 1328 [Dec 23] 1933). He examined many hairs in people who were turning gray gradually and found that the single hair changes its color rapidly—in a few days. Usually the change involved the whole length of the hair, but sometimes the proximal part next the root turned white while the rest retained its color, or even less frequently the tip became bleached while the lower part was still pigmented. He therefore rejects the theory of Bloch that the pigmented hair is shed and a white one grows in its place. He is convinced that loss of pigment occurs from some change within the hair. He acknowledges the possibility of sudden blanching.

These two clinical observations propose a fourth theory of the way in which hair turns gray. It presupposes a chemical change within the hair, bleaching the melanin as it is bleached by the outward application of hydrogen peroxide or by the action of ultraviolet radiation in Rothman's experiment.

Galewsky, one of the greatest authorities on diseases of the hair, comments (Canities, *Handbuch der Haut u. Geschlechtskr.*, 1932, p. 160) that in his extensive experience he has never seen a genuine case of sudden canities and thinks it strange that no such cases were reported during the first World War, when there was so much mental and physical distress. He overlooked the report of Vignolo Lutati (Premature Gray Hair and War Psychopathies, *Polichinco* 25 680, [July 21] 1918), who cites several cases occurring among the Italian troops. The rarity of these cases suggests that this phenomenon occurs only in those with a certain predisposition rarely brought to light by extraordinary stress. The same conditions were supposed in the cases of restoration of hair color in the answer to a query in *THE JOURNAL* Sept 27, 1941 p. 1140.

The fact that in rare instances hair can quickly become gray must be acknowledged. We need further proof of Landois's gas bubble explanation which is difficult to get, for so rare an event seldom occurs under the eyes of a trained observer. The old idea that hair is practically a dead tissue, cut off from the metabolic influences in the body, must be forsaken.

ERYTHEMA FROM WELDING

To the Editor—A patient who is a welder has severe erythema of the chest and abdomen. As there are no blisters I think the condition is actinic resulting from ultraviolet rays from the welding arc. I advised him to wear a black shirt. Can you advise any other protective measures?

E P S Miller, M D, Chicago

ANSWER—Erythema and even vesicles resembling sunburn have been reported as occurring among welders on the uncovered portions of the skin. This is said to be due to the actinic rays of the electric welding arc which are generated, especially in flashes.

The treatment consists in wearing clothing through which the rays will not penetrate or to apply protective ointments containing light screens. A suggested ointment would consist of zinc oxide ointment to which is added 10 per cent tannic acid or 5 per cent methyl salicylate. Such a protective ointment can be obtained from the West Disinfecting Company under the name of West Protective No. 88. This ointment contains titanium oxide and methyl salicylate.

VITAMIN D FOR CHILDREN IN SUNSHINE AREAS

To the Editor—One of my medical friends in Central America has written to ask about the use of vitamin D in light skinned children in the sunshine area of Guatemala. It seems to be fully recognized that vitamin D should be given at least during the first year and a half of life. After that period has elapsed and the child is playing a great deal and living exposed to suboptimal sun, is it necessary to continue vitamin D or is it advisable to do so?

Daniel Crasby M D Oakland Calif

ANSWER—Vitamin D other than that synthesized in the skin by the ultraviolet of sunshine should not be necessary for any infant or child living in a sunshine area of a tropical or subtropical region. It would be necessary only for those kept closely housed. It is probable that for many infants living in such a region a need for ingested vitamin D does not exist. The general tendency in the temperate zone is to give much more than is needed. If comparable amounts are given to babies exposed frequently to sunshine, the effect may be definitely detrimental in that after several months the appetite may decrease with consequent ill effect on nutrition.

PROBABLE LABYRINTHINE VERTIGO

To the Editor—A woman aged 36 has been having spells of vertigo for the past four months and I am curious about their relationship to her menses. The younger of her two children is 7 years of age. She has had no serious illness. There was an appendectomy eight years ago. Her periods have been quite normal and regular. Four months ago she had a sudden attack of dizziness, which grew worse as she turned her head or bent over. She was placed in bed for a few days and stimulants for a blood pressure of 104 systolic 76 diastolic were given. In five days she had recovered completely at which time the blood pressure was back to normal 120/78. The attack had come on one day after she finished her period. The next month was normal with no vertigo. During the last of June, one day before the end of her period she had a severe attack of vertigo with intense nausea vomiting and inability to stand when she attempted to arise in the morning. Turning of the head in any direction caused worsening of the condition. Blood pressure was 118/84 pulse 87 and respiratory rate 21. There was nystagmus only to the right, urine tests were normal, the Wassermann reaction was negative. There was no pain in the ears or around the mastoid or temporal regions. There was no tinnitus or other aural symptom. Two days before the July menses she was given corpus luteum by hypodermic injection each day and for two days after the menses began. On the fourth day of the period she had a minor attack of vertigo accompanied by some nausea and considerable weakness. The blood pressure was 114/76 pulse rate 82 and respiratory rate 20. At no time has there been any fever. Since there has been no aural pain and the attacks have been more or less coincidental with the last of the menses each month I should like to know whether there is anything which we might do to help with the diagnosis and treatment. Her blood count is normal. There seems to be no congestion of the liver, no dental infection and no other point of poisoning. M D, Arizona

ANSWER—The description of the vertigo would seem to put this phenomenon in the class of the true labyrinthine vertigo. This requires that all the usual causes of this disease be ruled out. Disease or degeneration of the auditory nerve must be considered. Cerebellar tumor is a possibility. If these and similar causes can be eliminated, the case falls into the speculative group. The relationship to the menstrual periods is suggestive. It is well known that there is often retention of fluids in the body during the menstrual period. This comes about through some obscure disturbance of the water balance. Disturbance of the water balance might easily produce a corresponding disturbance of pressure in the semicircular canals. This would be associated with a true labyrinthine vertigo.

A therapeutic test might be applied by attempting to control fluid retention during the menstrual period. The patient should be placed on a salt free diet. The sodium ion is particularly to be avoided. A week or two before the onset of the menstrual period, fluids should be sharply restricted. The fluid intake should be kept under 1,000 cc daily. Ammonium chloride in the amount of 6 to 8 Gm daily should be administered. The administration of antinutrin S has been found helpful. If this regimen, kept up for three or four months prevents the occurrence of the vertigo at the menstrual period, it would offer presumptive evidence that in this case the vertigo was caused by an increased pressure in the semicircular canals due to fluid retention of a disturbed water balance.

PREGNANDIOL EXCRETION IN PREGNANCY AND PROGESTERONE ADMINISTRATION

To the Editor—It is admitted that in case of amenorrhea few injections of progesterone will be followed by a false menstruation. The theory seems to be that when the action of progesterone on the uterine mucosa is ended there will be a so called withdrawal bleeding. But supposing that really the woman was in incipient pregnancy what will be the effect of the injections? If the pregnant woman will bleed like the others then there is danger of abortion. The physician therefore should not give an injection if he cannot absolutely exclude the pregnancy. Or the injections of progesterone will be without effect on the pregnant woman, because she has a good and continuous supply of progesterone from her corpus luteum and later from her placenta and therefore there is no withdrawal. I should like very much to know your opinion and the state of the literature on the subject.

M D New York

ANSWER—There is no harm in giving progesterone to a woman who is pregnant. In order to establish uterine bleeding through progesterone administration it is necessary that the progesterone level drop to a very low point, in other words, below the threshold for bleeding. The administration of the usual amount of progesterone would have no effect on a patient with amenorrhea who is unknowingly pregnant, since the withdrawal would not result in a drop below the bleeding threshold for progesterone because of the large amounts of endogenous progesterone in such a patient. There is no harm in the treatment of patients with amenorrhea by progesterone administration on the chance that there may be an occasional instance of amenorrhea due to pregnancy.

CLINICAL USE OF AMINO ACIDS FOR THE MAINTENANCE OF NITROGEN EQUILIBRIUM

SAMUEL S. ALTSHULER, MD
MELVILLE SAHYUN, PhD
HELENE SCHNEIDER, MD
AND
DANIEL SATORIO, BS
DETROIT

It has previously been shown that a mixture containing all the essential amino acids can be administered parenterally without untoward effect that amino acid mixtures so administered may be substituted for protein in the diet and that by this means a patient may be maintained in nitrogen equilibrium.¹ It has also been shown that the solution may be administered at the rate of 1 to 2 Gm. of amino acid nitrogen an hour and that, so administered, over 95 per cent of the amino acids was utilized in patients with malignant growths, hyperthyroidism, hypothyroidism, chronic infections, chronic nephritis or cirrhosis of the liver.

The present study was undertaken to extend the types of conditions in which solution of amino acids may be profitably used and also to observe the effect of this amino acid solution on the blood protein and blood amino acid level. The solution was administered orally, intravenously and intrasternally. The material used was an acid hydrolysate of casein with 1 per cent tryptophane added for parenteral use and an enzymatic hydrolysate for oral use. It is a 15 per cent solution containing 21 per cent nitrogen and was prepared by Sahyun.

For intravenous administration the amino acid solution may be diluted in two or three parts of isotonic solution of sodium chloride or in 5 or 10 per cent dextrose. The rate may be as rapid as 200 cc. of the amino acid solution an hour although this is influenced by the rate at which the diluent—for example, 10 per cent dextrose—can be given. In general, the rate is determined by the response of the patient. Should such symptoms as headache, flushing, dizziness or nausea arise, they may be abated by reduction of the rate of administration.

Amino acid solutions used in this study were furnished by Frederick Stearns & Co., Detroit.

From William J. Seymour Hospital, Eloise, Mich., and Wayne University College of Medicine, Detroit.

Read before the Section on Experimental Medicine and Therapeutics at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

2. Altshuler, S. S., Hensel, Hilda H., Hecht, Paul, and Purley, Richard. *Arch. Int. Med.* to be published.

Injection of amino acid solution into the bone marrow was done intrasternally with Turkel needles. The method was used on 3 patients and it was found that amino acids may be given by this route as rapidly as intravenously. The results were no different than those with the other methods, but intrasternal administration was advantageous in patients in whom access to the veins was difficult. The Turkel needles may be left in place for twenty-four hours or longer and repeated injections may be given through them.

For oral administration the amino acid solution was diluted in fruit juice or tomato juice. This method was just as effective as intravenous injection and clinically the ingestion of protein nitrogen in the form of amino acids gave a better result than did a high protein diet.

USE OF AMINO ACIDS IN SURGICAL CASES

In operative conditions such as gastric surgery in which the patient can take nothing by mouth for considerable periods before or after operation, it is possible to maintain adequate nutrition by the parenteral administration of amino acid solution and 10 per cent dextrose. Three such cases are included in the present series.

CASE 1—A man aged 70 after a posterior gastrojejunostomy was given intravenously 400 cc. (60 Gm.) of amino acid solution in 3,000 cc. of 10 per cent dextrose daily for five days. On the sixth day and daily thereafter he was given 200 cc. (30 Gm.) of amino acid solution in tomato juice plus a varying amount of protein in a soft diet. This continued until a gastric resection was performed one month after the first operation. Then postoperatively daily for the first three days the patient was given 200 cc. (30 Gm.) of amino acids in 3,000 cc. of 10 per cent dextrose. The patient made an uneventful recovery. Blood protein levels were maintained throughout.

CASE 2—A man aged 58 at operation was found to have a large carcinoma of the stomach with extensive metastases to the liver and omentum. Preoperatively daily for five days he received 400 cc. (60 Gm.) of amino acid solution in 5 per cent dextrose. Postoperatively he was given 400 cc. intravenously daily for seven days and then 400 cc. intravenously and 200 cc. orally for twelve days. The patient died three weeks after operation. The blood protein levels were 6.6 Gm. per hundred cubic centimeters before operation, 4.7 Gm. per hundred cubic centimeters on the eighth day after operation and 6.1 Gm. per hundred cubic centimeters four days before death. The addition of the oral amino acids after the seventh day helped raise the blood protein level, but it did not reach normal.

CASE 3—A man aged 26 was admitted with a diagnosis of acute appendicitis and was operated on the same day. He was found to have an acute ruptured appendix with diffuse peritonitis. He received 400 cc. of amino acid solution in 3,000 cc. of 10 per cent dextrose daily for the first six days. During this time he took nothing by mouth. For the next six days amino acid solution was given orally in fruit juice with a soft diet. The blood protein levels were 6 Gm. per hundred cubic centimeters on the first postoperative day, 6.1 Gm. per

hundred cubic centimeters on the seventh day and 67 Gm per hundred cubic centimeters on the fifteenth day. The patient made an excellent recovery.

During periods when these patients were taking nothing by mouth it was found to be most important that sufficient dextrose be given to supply the necessary

the case in which the transplant was made the wound healed, the patient gained 2½ pounds (1,134 Gm) and he was discharged feeling well. In the other case the wound healed satisfactorily.

CASE 8—A man aged 79 had a perineal prostatectomy which was healing very slowly, and a fecal fistula developed. A month after operation daily oral administration of 200 cc of amino acid solution was begun. An improvement was noted in the patient's general condition, and the wound healed more rapidly. The fistula was allowed to heal until a sinus tract developed. Two months later the sinus tract was resected and the wound healed well. In the two months preceding the second operation the patient gained 31 pounds (14 Kg).

CASES 9 AND 10—Two patients had sinuses following drainage of perinephritic abscesses. One patient had been operated on a month before amino acid therapy was begun. The other patient had been operated on five months before, the wound had healed and then ruptured to the surface over the flank about a month before. Daily oral administration of 200 cc of amino acid solution was started and in four weeks the sinuses of both patients were completely closed.

NONHEALING ULCERS

Ten nonhealing ulcers were studied. 2 of them in diabetic patients.

CASES 11, 12, 13 AND 14—Four patients had varicose ulcers of the legs of from seven months to two years' duration, one ulcer having recurred periodically for thirteen years. These patients were given daily 300 cc of amino acid solution orally for four weeks, by which time all the ulcers showed definite improvement (figs 1 and 2). One patient left the hospital and did not report to the clinic for his amino acid solution. Three weeks later a definite increase in the size of his ulcer was observed.

Fig. 1—Varicose ulcer of five months' duration.

calories. Otherwise the amino acids would be utilized for energy instead of for tissue repair.

The second group consists of 7 cases of nonhealing postoperative wounds.

CASE 4—A man aged 55 was operated on at another hospital for a ruptured gangrenous appendix and the incision became infected. On admission a secondary closure was performed. Four days later the wound was not healing and the peritoneum was visible. Intravenous administration of amino acid solution was begun and continued daily for eight days. Decided improvement was observed after four days of this treatment. Beginning with the ninth day amino acids were given orally for six days. The wound continued to heal and the patient made a good recovery.

CASE 5—A man aged 49 was operated on for umbilical and bilateral inguinal hernias. A separation of the umbilical and right inguinal incisions ensued which were then reoperated on. Eight days later the wounds disrupted. Intravenous administration of amino acid solution was begun and continued for five days after which the solution was given orally for eight days. A month later oral administration was resumed in preparation for a secondary closure, which was performed. Amino acid therapy was continued for five days. The following month the patient was discharged with wounds well healed.

CASES 6 AND 7—Two men with carcinoma of the penis had amputations performed and the wounds were healing very slowly for five weeks. One patient had a urethral transplant made beneath the scrotum. After the operation the margin of the transplant did not heal. Each patient was given daily 200 cc of amino acid solution orally for nineteen days. In

Fig. 2—Same ulcer shown in figure 1 after two months' treatment with amino acid solution.

CASE 15—A woman aged 64 had a decubitus ulcer of the leg due to pressure of a cast. Eleven months after removal of the cast the ulcer had not yet healed. She was given 300 cc of amino acid solution daily for three weeks, by which time there was definite evidence of healing.

CASE 16—A man aged 62 had a decubitus ulcer on the leg after removal of a cast. The condition had endured for six

months and the ulcer was spreading. Daily oral administration of 300 cc of amino acid solution was begun and after five weeks the ulcer showed definite improvement.

CASE 17—A woman aged 46 has a decubitus ulcer of the back of three years' duration. She has the tremor and facies of Parkinson's disease and has not walked for three years. Lying on her back has subjected the sacrum, knees and heels to constant pressure, which resulted in a large infected ulcer over the sacrum. Her daily temperature rises are to as high as 102 F. Oral administration of 300 cc of amino acid solution was begun and has been continued daily. The patient showed improvement for five weeks, but during the past week the ulcer has become larger and her general condition is poor.

CASE 18—A man aged 36, following gunshot wounds fourteen years ago, developed chronic osteomyelitis of the left ankle with ulcer. X-ray examination revealed rarefaction of the external malleolus. Two skin grafts were tried unsuccessfully. Amino acid therapy was given for three months, during which time the ulcer improved. When administration of amino acids was discontinued, however, the ulcer increased in size (figs 3, 4 and 5).

CASES 19 and 20—Two diabetic patients, a man and a woman aged 60 and 62 respectively, had ulcers of the feet, both had previously undergone amputation of the other extremity above

Fig 3 (case 18)—Draining ulcer recurring intermittently for thirteen years following gunshot wound.

the knee. The man had an ulcer on the lateral side of the foot of nine weeks' duration. The infection had been well cleaned but no healing was taking place. He was given 200 cc of amino acid solution daily by mouth and in three weeks was able to return to his work as a timekeeper. The woman had an ulcer of the big toe in which healing was imperceptible, although it had been clear of infection for about five months. After four weeks of daily oral administration of 200 cc of amino acid solution the ulcer was practically all filled in.

BURNS

Three cases of burns—2 of them extensive—were treated.

CASE 21—A man aged 52 had an infected third degree burn on the dorsum of the right foot with lymphangitis and lymphadenitis, and also first and second degree burns on the left leg. For six weeks healing had been very slow. Oral administration of 400 cc of amino acid solution was begun and continued daily for twenty-three days. The patient was discharged three weeks later with the burns nearly all healed.

CASE 22—A man aged 37 for seven months had been treated for first, second and third degree burns involving the left upper arm, shoulder, upper half of the trunk and left thigh. He had a daily rise of temperature ranging from 102 to 104 F. The wounds were healing very slowly. They were tender and the

patient seemed quite toxic. Administration of 100 cc of amino acid solution intravenously was started and continued daily for seventeen days. After this amino acid solution was given orally for three months, starting with 100 cc daily and gradually increasing to 400 cc daily. The patient improved rapidly, tenderness of the wounds disappeared and the burns healed very well (figs 6 and 7). The blood protein remained at normal values throughout.

Fig 4 (case 18)—Same ulcer after three months' treatment with amino acids.

CASE 23—A woman aged 27 had extensive burns on both upper and lower extremities, neck and part of the chest. She had been treated at another hospital and skin grafts had been tried unsuccessfully. She was given 300 cc of amino acid solution daily by mouth. The burns were healing fairly well but renal insufficiency developed and the patient died of uremia.

GASTROINTESTINAL CONDITIONS

Two patients had gastrointestinal conditions.

CASE 24—A man aged 75 had diverticulosis of the colon and duodenum with bleeding, macrocytic hyperchromic anemia and

Fig 5 (case 18)—Appearance of ulcer after amino acid had been continued for one month.

possible cirrhosis of the liver. He received a high protein diet and 200 cc of amino acid solution by mouth daily for three weeks. On admission liver function tests revealed impairment but later they were normal. On admission, laboratory findings were hemoglobin 11.5 Gm and red blood cells 2,940,000; after treatment they were hemoglobin 13 Gm and red blood cells

4,010,000. The blood protein level before treatment was 5.3 Gm per hundred cubic centimeters and after treatment 7.6 Gm per hundred cubic centimeters. The patient was discharged much improved.

CASE 25—A man aged 28 complained on admission of diarrhea with ten to twelve stools a day. The condition had

Fig. 6 (case 22). Burn of seven months duration.

persisted for about a year. He was given 200 cc of amino acid solution by mouth daily for thirteen days and was discharged much improved.

MUSCULAR DYSTROPHIES

Four patients were seen with muscular dystrophies.

CASE 26—A woman aged 48 with amyotrophic lateral sclerosis was not able to sit up at the time of admission. She was daily given 200 cc of amino acid solution orally for a month, then 100 cc orally for twelve days and since that time 200 cc daily. She is now able to be out of bed to walk and to help herself. The fibrillations are less pronounced.

CASE 27—A man aged 34 has had amyotrophic lateral sclerosis since 1938 with progressive disability. On admission he was completely bedridden and unable to care for himself, since he could not lift his arms. He had definite dysarthria and dysphagia and very coarse, ubiquitous fibrillations. He could scarcely be understood when he spoke. He was treated with prostigmine, potassium chloride and vitamin C none of which had any noticeable effect. He was given 200 cc of amino acid solution intravenously daily for a month after which administration was changed to oral. His condition improved to the point at which he was able to make himself understood, feed himself, smoke and tend to his personal needs. He is not able to walk but he can sit up without support. Fibrillations still persist but atrophy has not progressed. When administration of amino acid solution was discontinued his condition rapidly reverted to the former state. He was again given intravenous amino acid solution daily with decided improvement.

CASE 28—A man aged 52 had his condition diagnosed as amyotrophic lateral sclerosis three years ago, and since that time his course was downhill. He was given 200 cc of amino acid solution intravenously daily for three weeks, after which the administration was changed to oral. The patient shows definite improvement and has maintained his weight.

CASE 29—A man aged 52 had myotonia atrophica and diabetes. He was unable to take care of his own needs or even to turn over in bed without assistance. He was given 200 cc of oral amino acid solution daily for two weeks and the amount was then increased to 300 cc a day. The patient now can eat alone, take care of his personal needs and sit in a wheel chair.

BLOOD STUDIES

Plasma protein levels were determined on every patient receiving amino acid solution. It was found that the plasma protein level can be elevated or maintained at normal with the administration of amino acid solution providing there are enough calories furnished by the diet or in the form of dextrose. Otherwise the amino acids will be utilized for energy rather than for plasma or tissue regeneration. There is clinical and experimental evidence that amino acids as the sole source of nitrogen can regenerate plasma protein and can promote growth.³

The plasma protein levels did not always agree with the clinical results. Several patients who showed very

Fig. 7 (case 22). Same burns after five months treatment with amino acids.

fine clinical improvement did not have a corresponding rise in the plasma protein levels. This may be due to the influence on plasma protein levels of other factors.

such as infection, the state of hydration or the amount of protein reserve in the tissues⁵

The effect of the parenteral administration of the solution on the blood amino acid levels was also studied. Two male patients were given a diet containing 90 Gm of protein, and the blood amino acids levels were determined by Sahyun's method⁶ before breakfast and at intervals after meals. The levels were found to be con-

Blood Amino Acid Levels

	N/g./100 Cc
Fasting	10.2
½ hour	10.5
1 hour	10.6
1½ hours	10.9
2½ hours	10.4
3½ hours	10.0
4½ hours	9.9
5½ hours	9.9
6½ hours	9.8

stant. During the experimental period a fasting level was determined before breakfast, and immediately after breakfast administration of 200 cc of amino acid solution in 600 cc of saline solution was begun. This took an hour and a half. Blood amino acid levels were determined half an hour after administration had been completed and at intervals thereafter for six and a half hours and are given in the accompanying table.

The small accumulation of amino acids in the blood following parenteral administration of the solution indicates rapid utilization. These results were similar to Sahyun's findings on rabbits.⁷

COMMENT

The significance of protein to the body has been universally recognized by chemists, physiologists and physicians. However, until recently nothing could be done to supply this essential to persons who were unable to take an adequate amount of protein by mouth. The ability to furnish protein to the body parenterally by the use of amino acids is a real advance in the field of nutrition.

In operative cases the assurance of an adequate supply of protein is most important, first, to protect the liver from possible toxic effects of anesthesia, second, to prevent tissue edema, which interferes with healing of the wound, and third, to supply the essential nutrients required for tissue repair and regeneration.⁸

In the nonhealing ulcers and burns there was improvement in most cases after amino acid solution was given. The amino acids were not supplemented with vitamins because of the difficulty which would then arise in interpreting the results. For practical therapeutics, however, vitamins C and D should be used in conjunction with the amino acids to treat poorly healing wounds, ulcers and burns.

The clinical improvement of the patients with muscular dystrophies was quite striking. Problems still to be solved are how the amino acids produce this effect and why a relapse occurs when the amino acid therapy is discontinued.

CONCLUSIONS

1 Solutions of amino acids were used as the only source of nitrogen during preoperative and postoperative periods.

2 Poorly healing postoperative wounds, ulcers and burns were stimulated to more rapid healing by the use of amino acids.

3 The disabling symptoms of muscular dystrophies were abated during the time that the patients were receiving amino acid solution.

4 Solutions of amino acids were found to be equally effective when administered orally, intravenously or into the bone marrow. The latter method done intrasternally offers an excellent way of achieving parenteral injection when the veins are inaccessible.

ABSTRACT OF DISCUSSION

MELVILLE SAHYUN, PH.D., Detroit. We have been studying amino acids since 1937. Nutritionally amino acids are divided into two groups: (1) nonessential and (2) essential or indispensable. The latter consists of aliphatic amino acids (leucine, isoleucine, valine, methionine, threonine), basic amino acids (histidine, lysine, arginine) and aromatic amino acids (phenylalanine, tryptophan). While our knowledge of the indispensability of these amino acids is based on studies on animals, nevertheless we believe they are important and indispensable since the human system probably cannot synthesize them. One or more of these amino acids enters into the composition of different types of proteins. As an example, in insulin protein, the amino acid constituents of which are known we find that it contains of the essential group leucine, histidine, arginine, lysine and phenylalanine. Casein of milk contains all the indispensable ones. The good clinical results reported in this article may be attributable in part to the presence of essential amino acids in the preparation administered to the patients. It is possible that under certain conditions we may not be able to make available from the proteins of the diet, some essential amino acids required by the various organs of the body. As an illustration a molecule of protein may be likened to a table or a chair and the parts of each to amino acids. A carpenter equipped with proper tools (enzymes of the body) can convert a table to a chair, provided he has all the essential parts, or in a simpler way can build a chair or a table from prefabricated parts—amino acids.

DR. HARRY KOSTER, Brooklyn. I thought it might be interesting to add experiences with 25 cases in which nitrogen excretion was studied preoperatively and postoperatively. The patients were starved for three days before operation. The urine was collected and the total nitrogen was estimated. Then operation was performed. They received nothing for five or six days subsequent to the operation except dextrose and 120 Gm of amino acids administered intravenously daily. The total urine was estimated subsequently for total nitrogen and we found that it was possible to keep these patients in nitrogenous equilibrium. It seems to me that that is the important contribution that can be made at the present time. From a clinical standpoint one should be cautious about this sort of treatment. While, on an a priori basis, it might be considered that the supply of amino acids intravenously would be a beneficial thing, I don't think there is enough evidence to warrant any great enthusiasm. The important thing is that it is possible to keep a patient in nitrogenous equilibrium without providing transportation of the amino acids through the mucous membrane.

DR. SAMUEL S. ALTSHULER, Detroit. The cases which were presented are merely examples of early observations and I feel that we should study more cases over longer periods of time. There are many other possible uses of amino acids yet to be investigated. By giving proteins intravenously, deamination in the liver and absorption in the intestinal tract are eliminated. This may be the explanation of why administration of amino acids gives better clinical evidence of protein utilization than does ingestion of a high protein diet. However, this is among the problems yet to be worked out.

CUTANEOUS CHANGES IN THE SPRUE SYNDROME

WILLIAM H KAUFMAN, MD

AND

DUDLEY C SMITH MD

CHARLOTTEVILLE VA

The sprue syndrome has become familiar to physicians everywhere through the large literature¹ which has accumulated since its original descriptions by Hilary in 1759 and independently by Manson and by Van der Burg in 1880. While sprue is common in certain tropical countries which accounts for the designation 'tropical sprue,' recent publications by American and European authors have emphasized the importance of sprue as a widespread and frequently unrecognized disease of the temperate zone. From the many conflicting opinions of the past two fundamental concepts regarding the nature of sprue have emerged: (1) that celiac disease in children, tropical sprue and nontropical sprue are variations of a single disease complex, the sprue syndrome² and (2) that sprue is a disease often due to nutritional deficiency.³

Lesions of the tongue and oral mucous membranes in sprue have been well described and are regarded as of great diagnostic and prognostic importance by clinicians who have had wide experience with this disease. On the other hand, the often striking cutaneous changes have aroused relatively little attention, possibly because the widespread systemic disturbance overshadows the alterations in the skin. While resemblance is often superficial and confusion is usually eliminated by careful consideration of accessory data, the cutaneous changes in the sprue syndrome are to be differentiated from such pigmentary disorders of the skin as hemochromatosis, acanthosis nigricans, Addison's disease, arsenical pigmentation, xeroderma pigmentosa, chloasma and lentigo.

GENERAL CONSIDERATIONS⁴

Sprue is a chronic disease the clinical picture of which varies with its duration and with its characteristic remissions. The insidious onset of sprue symptoms is usually preceded by a long period of dietary imbalance consisting in a deficiency of proteins and an excess of carbohydrates and fats. Gradually there is progressive weakness, asthenia, irritability, mental depression, weight loss with muscular wasting and loss of the subcutaneous fat, abdominal discomfort, diarrhea with the passage of numerous grayish bulky, frothy, fatty, foul smelling soft or liquid stools, anemia, glossitis and stomatitis and in many cases hyperpigmentation of the skin.

Early in the course of sprue the anemia may be of the hypochromic microcytic type gradually becoming a hyperchromic macrocytic anemia indistinguishable from pernicious anemia. In contrast to pernicious anemia the stomach contains free hydrochloric acid in the majority of cases, a finding which is often of great

differential value. Paresthesias occur in some patients, although posterolateral sclerosis such as is seen in pernicious anemia is rare. Children with celiac disease show a hypochromic microcytic anemia.

The serum calcium and phosphorus are frequently low. Tetany and osteoporosis are seen in adult sprue while in celiac disease there are rachitic changes, dwarfism and tetany.

Thaysen⁵ has described a low blood sugar curve in sprue patients following ingestion of 1.5 Gm of dextrose per kilogram of body weight. This test is useful in differentiating sprue from other conditions with which it may be most easily confused.

The pathologic changes in sprue are not impressive.⁶ The fatty tissue of the body is depleted and there is atrophy and sometimes ulceration of the mucosa of the digestive tract.

Sprue responds dramatically to oral and intramuscular liver extract if treatment is not so long delayed that irreversible changes occur. The appetite returns, diarrhea ceases, the lingual papillae regenerate, and the patient gains weight and strength. There is a rise in reticulocytes in the circulating blood and with the assistance of iron a normal blood picture is established.

LESIONS OF THE MOUTH AND TONGUE

Lesions of the oral mucous membranes are found in the majority of sprue patients. It has been suggested by Manson⁷ that these mucosal changes reflect similar alterations in the entire digestive tract. Of the 34 cases of sprue collected by Thaysen⁵ there was stomatitis in 26. From a study of 92 patients 77 of whom had symptoms related to the tongue, Castle and his co-workers⁸ concluded that a diagnosis of sprue is almost impossible in the absence of glossitis and digestive disturbances.

According to Thaysen⁵ stomatitis occasionally is a presenting symptom but usually appears after the onset of diarrhea. He found stomatitis localized principally on the tongue manifested by swelling and redness of the individual papillae in a limited area at the tip of the tongue or on the lateral margins. Often there was burning and smarting of the tongue and troublesome salivation. The intensity of symptoms varied greatly and was apparently unrelated to remissions and exacerbations of the disease.

In Thaysen's cases the formation of aphthae was rare. When it occurred it was most often on the lateral edges of the tongue, less frequently on the inferior surface of the tongue and buccal surface of the lips. Manson, Bahr and Willoughby,⁹ however, found small aphthae on the buccal mucosa and tongue in 45 or 22.5 per cent of 200 cases and Low¹⁰ described aphthae in 101 or 67 per cent of 150 cases.

Bahr¹⁰ has described the sequence of events taking place in the tongue. The sides and tip of the tongue were first involved with inflammation and swelling of the fungiform papillae. Minute ulcers appeared which after healing left areas in which papillae were absent.

The filiform papillae disappeared, and fungiform papillae became visible as prominent red spots. In 2 cases observed by these authors, hemorrhages occurred in the corium of the fungiform papillae, forming hemorrhagic vesicles. Finally the fungiform papillae were destroyed. Longitudinal and transverse fissures appeared, and fissuring occurred at the corners of the mouth. Post-

Fig 1—Right anterior tibial region showing rough dry hyperpigmented skin with more deeply pigmented macular lesions

mortem microscopic examinations of two sprue tongues showed atrophy of the lingual papillae with only the bases of the fungiform papillae remaining. There was denudation of the surface epithelium and invasion of yeast cells. Mackie and Fairley,⁹ however, found no penetration of the mucosa of the tongue with the hyphae of monilia.

CUTANEOUS CHANGES

It would appear from the literature that alteration of the skin in sprue occurs in a high percentage of cases. This aspect of the disease has received but scant attention.

Bahr¹⁰ described a dark brown, irregular, patchy pigmentation resembling exaggerated freckles, distributed to the forehead, cheeks, abdomen, anterior thighs, legs and scapulas.

According to Thaysen¹² the skin in sprue is pale, grayish yellow or yellow brown but not icteric, dry, without turgor and slightly scaly. Cutaneous pigmentation was noted in 12 of his 34 cases. In 5 cases there were diffuse, scattered brown patches. Two cases resembling chloasma, with pigmentation localized to the face. In 2 cases pigmentation was localized on the abdomen. In 1 case pigmentation was so deep that the case resembled Addison's disease. One patient had dark brown spots, 2 cm in diameter, scattered over the entire body. Three severely anemic patients had petechiae. Brittle, frayed nails in 2 cases, and edema of the skin were also mentioned by this author.

Skin lesions were noted in 7 of 15 cases reported by Bennett, Hunter and Vaughan.¹¹ The eruption in several cases was confused with psoriasis, pustular dermatitis and eczematoid dermatitis. In 1 case there were

large moist, red abraded areas 2 to 8 cm in diameter with scaly, brown pigmented borders which resembled pellagra and cleared up after three weeks' treatment with brewers' yeast. In this case the skin lesions were so severe as to be the presenting symptom.

Snell¹² has commented on the resemblance of the hyperpigmentation of sprue to pellagra and acanthosis nigricans. Only 10 of 32 cases studied showed no pigmentation. In the remaining 22 cases there were pigmentary eruptions of varying degree. Petechiae were noted in 2 cases. In 2 cases there was eruption resembling pellagra. Diffuse melanosis was present in 1 case. Urticaria occurred in 1 case. Lackluster hair, brittle nails and clubbed fingers were common.

Thaysen,¹² in a series of 10 cases of sprue, described 7 in which symmetrical hyperpigmented patches occurred on the forehead and the nose and below the eyes. In several of these cases pigmented patches were present on the cheeks, and pigmented streaks from the angle of the jaw to the cheeks. Distribution of the eruption in 2 cases was so characteristic as to suggest the diagnosis.

A diagnosis of sprue was made in 6 cases studied in the medical service of the University of Virginia Hospital between 1927 and 1940. The records of these cases were reviewed.

Glossitis was noted in 5. In 2 no pigmentary changes in the skin were described. Four cases showed decided cutaneous changes characterized by melasticity, dryness and scaling of the skin. In 1 a patchy brownish, pigmentary eruption was present on the extensor surfaces of the arms, legs and dorsum of the hands. One case showed universal yellowish pigmentation with hyper-

Fig 2—Face showing chloasma-like eruption

pigmented patches on the dorsum of the hands. One case showed generalized yellowish pigmentation. The case reported displayed universal pigmentation with superimposed localized hyperpigmentation.

13 Thaysen T E H. Ten Cases of Idiopathic Steatorrhea. *Quart J Med* 4: 359 (Oct) 1931.

Autopsies were performed on 2 of the 3 patients who died. No significant changes were noted in the adrenals of these patients. 1 of whom had pigmentary changes, in the other no cutaneous changes were described.

While 6 cases do not represent a large experience consideration of the clinical and histopathologic studies in 1 case has afforded an opportunity to form certain conclusions regarding the nature of the cutaneous changes in sprue.

REPORT OF CASE¹

A white married woman aged 26 was admitted to the medical service of the University of Virginia Hospital on Oct. 26, 1940 complaining of weakness and of numbness and tingling in the arms and legs of two and one half years duration. Weakness and fatigability increased accompanied by pallor of the skin and severe transitory pains in the lower legs. These symptoms progressed with occasional remissions and exacerbations until April 1939, at which time she began to experience severe precordial pain, with exertional dyspnea and palpitation requiring bed rest. In April 1940 the patient had a rapid onset of persistent diarrhea accompanied by abdominal dis-

Fig. 3.—Section of skin of right lower leg, showing heavy deposit of pigment in the rete and basal cell layer. Foot's silver technique.

tention with the passage of four to eight bulky, foul smelling, soft or liquid stools daily. In June 1940 she began to experience soreness of the mouth and tongue, bleeding of the gums and painful ulcers of the mouth and tongue. At this time she noticed her skin becoming darker, with a brownish patchy eruption on the face, shoulders, arms and legs.

In spite of a good appetite and a diet containing adequate amounts of milk, eggs, fresh meat and vegetables (according to her story) she experienced a weight loss of 20 pounds (9 Kg.) during her illness.

The family, marital and past histories were irrelevant.

On admission the temperature was 100.1 F., the pulse rate 100, the respiratory rate 22 and the blood pressure 90 systolic and 60 diastolic. The patient was extremely emaciated. The skin was loose, rough and dry with universal yellow brown pigmentation. There were numerous irregular, discrete and confluent patches of deep brown pigmentation varying from 0.5 cm. to 5 cm. in diameter symmetrically distributed to the cheeks, nose, scapular regions, extensor surfaces of the forearms and lower legs and dorsum of the hands and feet. There were confluent hyperpigmented patches on the forehead and malar regions resembling chloasma. The mucous membranes were pale. The tongue was red and slick and the fungiform and filiform papillae were absent. There was decided gingivitis.

The cervical lymph nodes were palpable. The lungs were normal. There was a soft murmur following the first heart sound, heard best in the third left interspace. Rhythm, size, shape and position of the heart were normal. The tip of the spleen was palpable. The deep reflexes of the knees and ankles were hyperactive. Neurologic examination was otherwise normal.

The hemoglobin was 5 Gm. per hundred cubic centimeters (Haden), red blood cells 1,620,000, white blood cells 6,400 with 61 per cent polymorphonuclears, 2 per cent eosinophils, 28 per cent small lymphocytes, 3 per cent large lymphocytes and 6 per cent monocytes. Reticulocytes were 94 per cent. The color index was 1.08. The volume index was 12, hematocrit 16. The average cell size was 8 microns. There were numerous macrocytes in the stained blood smear. The blood Wassermann and Kahn reactions were normal. The urine was normal. Gastric analysis showed 45 degrees of free hydrochloric acid after subcutaneous injection of histamine. The icterus index was 10. Serum calcium was 10.3 mg. and phosphorus 6.4 mg. per hundred cubic centimeters. Plasma chlorides were 620 mg. per hundred cubic centimeters. The blood proteins totaled 5.8 Gm. per hundred cubic centimeters. Fasting blood sugar was 100 mg. per hundred cubic centimeters. A test for dextrose tolerance (oral) showed a flat curve with a maximum rise of 92 mg. per hundred cubic centimeters after one hour. A test for adrenal insufficiency as standardized by Cutler, Power and Wilder¹⁴ was well within the limits of normal with 10 mg. of chloride ion per hundred cubic centimeters of urine obtained on the specified routine. Sudan III stains on the stool showed definite increase in fat. Roentgenograms of the gallbladder and gastrointestinal tract disclosed no abnormalities.

The patient's temperature and pulse rate became normal within twenty-four hours after admission. On intramuscular and oral liver extract the reticulocytes rose to 12 per cent and the patient gained weight (5½ pounds or 2.4 kg.) and strength. During her stay she passed from one to four stools daily except during the period of preparation for a gastrointestinal series when she passed eight stools.

At the time of discharge, Nov. 22, 1940, the hemoglobin was 10 Gm. (Haden), red blood cells 3,120,000, white blood cells 7,800, color index 1.1, volume index 13, hematocrit 37, average cell size 7.5 microns, reticulocytes 0.9 per cent. The diffuse patchy pigmentation of the face, shoulders and extremities had diminished considerably at the time of discharge. Examination one month after she left the hospital revealed a 50 per cent diminution in the intensity of the generalized pigmentation with the disappearance of many of the larger hyperpigmented patches. No further clinical observation have been possible.

HISTOPATHOLOGIC OBSERVATIONS

A biopsy was made on the lateral middle third of the right tibial region. The excised tissue included several deep brown macular patches with a generous portion of the less deeply pigmented surrounding skin. The lower legs were free of such varicosities and stasis dermatitis.

The following histopathologic data were based on microscopic studies of sections fixed in 10 per cent solution of formaldehyde and embedded in paraffin. The following stains and combination of stains were used: hematoxylin and eosin, Van Gieson's picric acid and fuchsin stain¹ for connective tissue, the prussian blue reaction (after Kyes)² for hemosiderin,¹⁰ counterstained with Mallory's basic fuchsin for hemofuscin¹⁰ and Foot's silver technique¹ for melanin.

The cutaneous surface was thrown into numerous folds. There was slight loosely lamellated hyperkeratosis. The stratum granulosum was normal. Sections of the tissue stained with

hematoxylin and eosin showed heavy deposits of light brown, finely granular pigment in the cells of the basal layer. At intervals in the basal cell layer the pigment concentration was more intense. In these areas, collections of pigment laden rete cells extended far upward in the malpighian layer, forming a lenticle. The presence of hemosiderin (iron) was not demonstrable by the special stain. The silver stain without counterstain showed many fine pigment granules stratified longitudinally throughout the stratum corneum. The rete cells contained small numbers of fine, round or ovoid pigment granules. The lenticular collections, already described, showed heavy pigmentation. There were many fine round or ovoid pigment granules in the columnar basal cells, with concentration of pigment in the upper portion of the cell, "capping" the nucleus. A few dendritic cells, laden with pigment, were arranged between the palisade basal cells. No abnormalities were seen in the corium.

COMMENT

In sprue the glossitis stomatitis and fissuring at the corners of the mouth (ariboflavinosis) respond favorably to liver extract and appear to be related to a deficiency of the vitamin B complex.

The role of avitaminosis in the production of pigmentary changes requires further investigation. Anorexia, the damaged intestinal mucosa and the rapid passage of intestinal contents through the digestive tract operate to produce an extreme degree of vitamin deficiency. There is no doubt that a deficiency of the fat soluble vitamins occurs in patients with steatorrhea.¹⁸ Certain components of the skin changes in sprue, such as roughness and dryness of the skin with follicular keratosis, may be due to avitaminosis A. Some observers¹⁹ have suggested that the low values for serum calcium and phosphorus may be due to failure of absorption of vitamin D and to interference with vitamin D manufacture in the skin.

There has been much speculation regarding the nature of the cutaneous pigment. Since the icterus index is rarely elevated,²⁰ excessive hemolysis appears to have little if any part in the production of pigment. In the case reported the icterus index of 10 was not regarded as significant. The skin pigment does not give the reaction for iron.

Thaysen⁵ has reviewed the literature dealing with the relationship of sprue to inadequate functioning of the adrenal cortex. Pigmentation, hypotension and adynamia, which occur so constantly in Addison's disease, are also found in a high percentage of sprue cases. In sprue these symptoms subside during remissions, and, as Thaysen has pointed out, no anatomic changes have been demonstrated that would suggest that sprue gives rise to Addison's disease. The case reported shows no abnormality of that part of the adrenal cortex involved in electrolyte metabolism.

The histopathologic features of this case, showing an increase in the melanin content of the basal cell and rete layers, support Thaysen's theory⁵ expressed in the following quotation: "The chemical nature of the pigment is as yet quite unknown, but I find it not unreasonable to regard this pigmentation as an increase of the normal skin pigment."

Differential diagnosis of cutaneous pigmentation in sprue should offer no great difficulties.

Glossitis pigmentation and favorable response to liver extract are characteristics common to pellagra, sprue and pernicious anemia. In pellagra the body weight is usually maintained, anemia is seldom severe and the cutaneous erythema, scaling, fissuring and crusting are limited to surfaces exposed to irritation or to the sun's rays. Follicular keratoses and cheilitis due to riboflavin deficiency are frequently seen. Diarrhea and neurologic changes are usually present. The histopathologic picture in pellagra varies according to the stage of the disease. There is perivascular cellular infiltration in the corium, hyperkeratosis, parakeratosis and increased pigmentation in the basal layer and sometimes atrophy of the corium and epidermis.

The skin of pernicious anemia is diffusely icteric. Microscopic examination shows the presence of iron pigment. Achlorhydria occurs in all cases, while gastrointestinal symptoms are relatively uncommon. Combined degeneration of the spinal cord seen in 5 per cent of the patients with pernicious anemia frequently indicates the diagnosis.

The clinical and histologic features of acanthosis nigricans, Addison's disease, hemochromatosis and arsenical pigmentation have been described in detail by Montgomery and O'Leary.²¹

Acanthosis nigricans may be easily differentiated from sprue pigmentation by the symmetrically distributed verrucous pigmented patches which show a characteristic histopathologic picture and by the frequently associated neoplasm.

The pigmentation of Addison's disease may be indistinguishable clinically and histopathologically from sprue. Pigmentation of the mucous membranes of the mouth in patients with Addison's disease may be of differential value. The tendency of patients with Addison's disease to excrete urine containing chloride in high concentration has been found of diagnostic significance.¹⁴

In addition to the systemic changes of hemochromatosis, microscopic examination of the skin discloses deposits of hemosiderin. Arsenical pigmentation may be differentiated from sprue by the history of arsenical medication and by chemical determination of the arsenic content of the skin and urine. Microscopically, arsenical pigmentation shows hyperkeratosis and atrophy with inflammatory reaction in the papillary portion of the corium, whereas sprue, Addison's disease, chloasma and lentigo show only an increase in melanin content. Xeroderma pigmentosum, which shows pigmentation, atrophy, hyperkeratosis and formation of cutaneous carcinoma, can be easily differentiated from sprue pigmentation.

SUMMARY AND CONCLUSIONS

Stomatitis and glossitis with papillary atrophy are a constant feature of the sprue syndrome.

In a high percentage of cases of sprue the skin is rough, loose, dry and universally hyperpigmented, with a superimposed hyperpigmented macular eruption resembling chloasma. While variations in the intensity of the eruption are to be expected, in its fully developed form the cutaneous changes may often suggest the diagnosis.

Histopathologic alterations, consisting of excessive deposits of normal skin pigment (melanin) in the rete and basal cell layers, are not specific.

ABSTRACT OF DISCUSSION

DR J LAMAR CALLAWAY, Durham, N C Drs Kaufman and Smith have thoroughly studied their series of sprue patients from an angle hitherto only casually observed. During the past five years I have observed some 10 patients with sprue, and although certain of these patients had rough, loose, dry, somewhat hyperpigmented skin I have not been impressed with anything approaching a specific cutaneous picture such as is presented for example, by pellagra. In the majority of sprue patients there is a multiple vitamin deficiency and the cutaneous lesions were many times merely a manifestation of a generalized avitaminosis and not specific for the sprue syndrome itself. A review of records of 65 patients who were studied at Duke Hospital by Dr Fred M Hanes revealed that only occasional mention of pigmentation and cutaneous changes was made other than that the skin was loose, dry and somewhat scaling. However, these records were made by the regular house staff which was not particularly cognizant of the cutaneous changes or interested in them. In several instances pigmentation suggestive of chloasma localized over the face was noted and in 1 case the skin was distinctly yellowish brown with a follicular hyperkeratosis over the body giving to the skin a rough coarse feel which was described as like that of a shark's skin. There was no actual erythema but the limbs and wrists presented a pigmented appearance. Several of the cases reported by Drs Kaufman and Smith showed a yellowish pigmentation and the exact significance of this in their cases or ours is not clear. The stomatitis, glossitis and papillary atrophy appear at all times to be a constant feature of the sprue syndrome. I agree with their description of the signs and symptoms of the sprue syndrome, their interpretation of the etiologic factors responsible and their therapeutic regimen. It has been suggested that the atrophic condition of the subcutaneous tissue as a result of fat loss may be responsible in some way for the generalized cutaneous appearance of the patients. In the microscopic sections that I have reviewed the general appearance is much the same as those described by the authors. There is some hyperpigmentation, atrophy of the entire skin and appendages with a moderate round cell infiltration. I did not grasp the significance of the histologic picture but in the future I will be more observing of the clinical and histopathologic features of sprue patients.

DR HERMAN SHARLIT, New York I will offer an explanation for hyperpigmentation under all circumstances in which it may occur, based on observations in cell metabolism in such cells as can normally produce pigment. A living cell naturally must have oxygen to survive. The oxygen that reaches the cell is chiefly acquired by the primary respiratory system, which gives us our ordinary system of cellular respiration and which we can readily measure by the manometric method. Any other system of reaction in the cell requiring oxygen takes second place to this primary system in the integral organism. However as soon as a piece of tissue is removed from the body that tissue is moribund. It is dying and the first system which begins to show the evidence of this morbidity is the primary respiratory system. As this system loses in power loses in ability to operate at optimum other systems requiring oxygen can then operate more effectively. In other words as soon as the oxygen potential in the cell becomes reduced some other systems requiring oxygen can be more effective. One of these systems involves the production of pigment so that in metabolic experiments on skin, where an effort is made to minimize the amount of oxygen available to the cell in other words to render the oxygen potential in the cell lower, the effect is one of provoking pigment production in epidermal cells. It is possible—and we have demonstrated it in our laboratory—to provoke pigment production in biopsy skin tissue in an atmosphere of nitrogen just as effectively as in an atmosphere of oxygen, the meaning of this is that, in the laboratory procedure of accelerating pigment formation in epidermal cells, atmospheric oxygen is not necessary. In other words, while it is not an anaerobic process, the amount of oxygen that is actually required within the cell can best be utilized when the oxygen potential therein is at a minimum. I would ask those who observe pigmentation

to see whether they cannot be clinically impressed with the fact that in these cases, whatever the disease in which hyperpigmentations occur, we are dealing with partial anoxemia in the tissues. In the cases just reported in which desperation for air causes rapid respiration, the cells are operating under a state of partial anoxemia, and this status can readily explain the pigmentation in these cases, if correct, it will tend to explain most hyperpigmentation.

DR PAUL GROSS, New York Considering the skin changes in sprue from the dermatologic point of view, one can readily see from the clinical description by the authors and the histopathologic aspects outlined by Dr Callaway that the pigmentary changes are associated with an inflammatory reaction of the skin. It was this combination which prompted Erich Hoffman to speak of melanodermatitis toxica rather than of melanosis (Richl) when describing the peculiar pigmentary changes observed in certain persons during the first world war. This disease was considered a nutritional disturbance, and I have in the last two years observed a patient who presented a typical picture of melanodermatitis toxica. The hyperpigmentation was confined to the exposed parts, namely the dorsum of the hands, the extensor surface of forearms and the face, especially the perioral region. The patient had a microcytic anemia but no clinical signs of intestinal sprue. She responded well to intramuscular liver therapy but had two mild relapses a few months after liver therapy had been discontinued. It is not possible to say what deficiency is responsible for the melanosis but the disturbance of intestinal absorption in sprue apparently represents one of the mechanisms which produce these peculiar skin manifestations.

DR L. MARY STANISH, Hartford Conn Apparently sprue is not uncommon in some other parts of the country. At a clinic in New York an interesting case of sprue was shown. The cause was definitely multiple vitaminosis. The woman, a Greek restaurant owner, had been eating irregularly. The case, undiagnosed for several weeks was first recognized by the extreme loss of weight and weakness. She had not only the red atrophic tongue but also the shark skin and some pigmentation. She failed to improve on a diet and with heroic doses of vitamin B complex. Thorough blood work was done including frequent tests for fat and cholesterol. Daily fat estimations in the stool were made. Then they began to give vitamin A in large doses. They gave the amazing amounts of 5000-6000 units of vitamin A obtained by a new process. They found that this was the only factor along with a much reduced fat diet that controlled the patient. She is still being followed carefully by the Rockefeller Institute and the New York Hospital group.

DR MIRIAM T. R. MANNING, San Jose Calif In considering all these cases of intestinal and absorptive deficiencies, in which we can include chronic disease, sprue, chronic diarrhea, colitis and pernicious anemia we should consider why the patient has these symptoms. We should go into the patient's history and find out whether or not he had symptoms primarily which suggested an achlorhydria or whether his diet at that time was deficient. Sprue one might say, is the end result of multiple vitamin deficiency and the picture as described today is one of the B complex deficiencies. One may see a dominant A deficiency factor or one may see a dominant nicotinic acid deficiency factor or a riboflavin deficiency factor but the thing that one has to treat is the patient's absorptive ability, which many times is so damaged by atrophy that he cannot absorb these things by mouth and one has to use injections. Incidentally, this patient apparently also shows a C deficiency. I think that Dr Gross will agree that the action of vitamin C and the oxidation process of cells is important in the production of pigment but riboflavin is slow in its effect, nicotinic acid is rapid. If vitamins are given by mouth and there is considerable atrophy of the mucous membrane one has to give the patient time to absorb them and then to regenerate the papillae. Finally more rapid absorption will begin until, if one is giving larger doses they absorb so fast that the effect is of overdosage. The crude liver extract is more effective by injection than is the refined liver extract and is probably a better method of

handling these cases in the early treatment rather than pushing so much medication by mouth. Later when one begins to get papillae back on the tongue one may give the medication by mouth and discontinue the injections. The whole thing is an internal medical problem primarily. It is necessary to correct the achlorhydria that is primary, correct the dietary deficiency and finally treat effectively and not with too small doses and with full consideration of the pathologic changes found.

DR DUDLEY C SMITH, Charlottesville, Va. There are many interesting cutaneous and medical problems associated with this condition. The relationship to pernicious anemia, of course, is very close. Whether or not the hemopoietic principle in liver is the curative factor for sprue is not known. There are many other important problems and relationships to be worked out.

INSULIN RESISTANCE DUE TO INFECTION IN DIABETES MELLITUS IN MAN

JAMES A. GREENE, M.D.

IOWA CITY

AND

CAPTAIN G. T. KEOHEN

MEDICAL CORPS, ARMY OF THE UNITED STATES

Infection is probably the most common of the several causes for insulin resistance in diabetes mellitus in man, but the mechanism of this phenomenon is not understood. There are several theories which have been advocated to explain this resistance: (1) decrease of endogenous insulin secretion by the pancreas,¹ (2) decrease of effectiveness of endogenous and exogenous insulin,² (3) increase of metabolic rate,³ (4) greater glycogenolysis by the liver,⁴ (5) increase of epinephrine secretion by the adrenal,⁵ (6) decrease of insulin kinase secreted by the liver,⁶ (7) increase of adrenal cortex secretion,⁷ (8) increase of secretion by the anterior lobe of the pituitary gland,⁸ (9) increase of secretion by the thyroid gland,⁹ (10) decrease in ability of the skeletal muscles to form glycogen⁸ and (11) increase of inhibitory action on insulin of the blood plasma.⁹

The present investigation was undertaken in hopes that the data might be of some value in understanding this mechanism. Therefore we studied the reaction of the diabetes in controlled cases to the following conditions: (1) different types of infection or idiopathic fever, (2) injections of foreign proteins, (3) fever induced by the cabinet method, (4) repeated administration of histamine and (5) repeated administration of epinephrine. The urine of all the patients used in this study was rendered free of sugar in the hospital before the infection or fever developed or the aforementioned methods of study were instituted.

There were 24 patients who contracted an infection or an idiopathic fever while in the hospital after the diabetes had been adequately controlled. Typhoid vaccine was administered intravenously in doses of from 1 to 60 million bacteria to 14 patients. Fever was produced by the cabinet method six times in 4 patients. Histamine was administered in doses of $\frac{1}{40}$ gram (0.0016 Gm.) subcutaneously every four hours for two days to 2 patients, and epinephrine in doses of 0.5 cc. was administered intramuscularly every four hours for two days to 2 patients.

The degree of resistance was classified as slight, moderate and severe. If the insulin had to be increased 15 units or less to control glycosuria the resistance

Absence of apparent relationship between the presence or degree of insulin resistance and the average height and duration of the fever.

was called slight, an increase of 15 to 30 units was called moderate, and an increase of 30 or more units was called severe. In some instances the insulin was not increased or it was not increased sufficiently to prevent glycosuria. In such cases a glycosuria up to 20 Gm. was considered to be a slight resistance, 20 to 50 Gm. as moderate and above 50 Gm. as severe.

RESPONSE OF PATIENTS TO INFECTION

Of the twenty-eight observations on 24 patients who contracted infection or idiopathic fever, insulin resistance was not demonstrable in 10, whereas it was slight in 8, moderate in 4 and severe in 6. There was no apparent relation of sex, age or the duration of the diabetes to the development of insulin resistance. Mild or moderate diabetes, on the other hand, is more likely than severe diabetes to require more insulin during a toxemia, as shown in table 1. It is to be noted from table 2 that there was no relationship between the degree of fever and the degree of insulin resistance.

The greatest rise in body temperature may not be a good index of the severity of toxemia, because it may not persist for a sufficient time to alter the carbohydrate metabolism. It was for this reason that the average height of the fever and the degree of insulin resistance

were plotted with the duration of the fever. No definite relationship was observed. Two of the cases having the longest duration of fever also showed extreme increases of insulin requirement, but in one of these the insulin resistance had almost disappeared before the fever subsided. It is very common to observe insulin resistance appearing one to four days before any other evidence of infection, on the other hand, some cases do not require more insulin until several days after the infection is manifest, while in others the two appear simultaneously. In our cases the resistance developed before the fever in 2 instances, simultaneously with it in 5 and after in 9. There appears to be no relationship between the onset of insulin resistance and the onset of toxemia to the degree of alteration of insulin requirement.

The toxemia in 21 of our cases was due to infection, in 4 it was not due to infection and in 3 it was doubtful. A case of gastric hemorrhage due to a peptic ulcer presented a slight resistance and 1 with coronary occlusion a moderate resistance. All of the extremes occurred in cases of infection. Of the organisms known, streptococci were present in 5, tubercle bacilli in 1, *Escherichia coli* in 3 and pneumococci in 2. Not one of the infecting organisms showed any constant alteration of the insulin requirement. There was also no relation of the insulin sensitivity to the pathologic condition present, as shown in table 3. It is possible that the degree of toxemia is not measured accurately by the foregoing factors. It was for this reason that the mortality rate was compared with the presence and degree of insulin resistance. It is to be noted from table 4 that all of the patients showing slight insulin resistance

survived, death ensued in 1 case showing moderate and in 2 with no insulin resistance, whereas 4 of the 6 cases with severe resistance ended fatally. It is difficult to evaluate these 4 cases. In 1 of the 4 requiring great increases of insulin the resistance had almost disappeared before death, and in another the insulin requirement was not altered for the first twenty-three days but increased gradually during the last five days before death.

RESPONSE TO INTRAVENOUS ADMINISTRATION OF TYPHOID VACCINE

Of the 14 patients who received typhoid vaccine, 1 received two courses. The number of injections varied from one to ten in the different cases. In depancrea-

tized dogs Greene, David and Johnston¹⁰ found that it was frequently necessary to administer typhoid vaccine repeatedly in some instances to produce insulin resistance, but the development of resistance was not related to the number of injections. Insulin requirement was not altered in 3 of the patients and was increased slightly in 6, moderately in 4 and extremely in 1. There was no relationship between the presence and degree of insulin resistance and the number of injections of typhoid vaccine, as shown in table 5. The presence and degree of insulin resistance were also not related to the height of the fever as shown in table 6. An analysis of the response of each patient to each injection of typhoid vaccine revealed that slight insulin resistance developed even without the presence of fever. These data are shown in table 7. Of the 18 instances in which fever was not produced a slight increase of insulin requirement was noted in 8. In those in which fever was produced there was no alteration of insulin requirement in 13, whereas varying degrees of resistance were present in 23 instances.

RESPONSE TO FLUKE INDUCED BY CABINET METHOD

There were six observations on 4 patients whose diabetes had been controlled adequately before fever therapy. The effect of such therapy on the development of insulin resistance is shown in table 8. Insulin resistance developed to a slight degree during two of the

10. Greene, J. A., David, Ann and Johnston, George. Production of Insulin Resistance in Depancreatized Dogs. *Am. J. Physiol.* 136: 595-599 (June) 1942.

six observations. One patient exhibited none during the first treatment but required a slight increase in insulin during the second. As in the previous groups there was no relationship between the height of the fever and the presence or degree of insulin resistance. Two of the patients had previously received typhoid vaccine, and their temperature curves were duplicated in the cabinet. It is of interest that 1 showed slight resistance following typhoid vaccine injection, but none with the fever therapy. The other patient required a severe resistance with typhoid vaccine, whereas it was only slight with fever therapy.

The insulin requirement of the 2 patients who received histamine or of the 2 who received epinephrine was not altered.

COMMENT

A decrease of endogenous insulin secretion by the pancreas is the theory which has been most widely accepted. The work of Greene, David and Johnston¹⁰ which showed that insulin resistance can be produced in depancreatized dogs makes this theory untenable.

Another theory which has been fairly widely accepted is that the increase in metabolic rate accounts for the insulin resistance during an infection. Our observations cast a good deal of doubt on this theory. The presence and the degree of insulin resistance were not

that produced by the cabinet method casts further doubt on this theory. These observations convince us that the fever is of minor significance in the production of insulin resistance. That the toxemia was more important has been suggested by Rabinowitch¹¹ and others and is supported by our observations. The term tox-

related to the height or duration of the fever in our cases with infection following typhoid vaccine administration or during and following fever induced by the cabinet method. In addition, some of our cases manifested slight resistance following typhoid vaccine injections without the appearance of fever, whereas, others showed none even though the body temperature rose 4 and 6 degrees. The difference in response of 2 cases to fever produced by typhoid vaccine administration and

emia, however, is vague and does not explain the mechanism of this phenomenon. Depletion of the sugar stores of the body undoubtedly plays some role in certain cases of insulin resistance, as emphasized by Greene and Swanson,¹² but it is not the principal factor. An increase in the secretion by the thyroid has been thought to account for a greater insulin requirement, but Greene and Swanson¹³ have previously shown that the hyperglycemia and glycosuria in cases of hyperthyroidism without diabetes mellitus can be eradicated by a diet high in carbohydrate and can be reproduced by a diet low in carbohydrate and high in fat.

Insulin resistance has been attributed to an increase of epinephrine secretion by the adrenal gland. It is generally recognized that hyperglycemia and glycosuria frequently follow the administration of epinephrine and in cases of pheochromocytoma, hyperglycemia and glycosuria are found during an attack of paroxysmal hypertension. The administration of epinephrine every four hours for two days in 2 of our cases, however, failed to produce any evidence of insulin resistance. It is readily admitted that the dosage may have been inadequate, but subjective and objective manifestations of epinephrine effect were produced in both cases. Such evidence is against insulin resistance being due to an increased epinephrine secretion by the adrenal gland.

The fact that the dogs described by Greene, David and Johnston¹⁰ developed insulin resistance coincidentally with the greatest tissue reaction in a cellulitis produced by subcutaneous administration of turpentine suggests that a histamine-like substance may be liberated by the inflamed tissue and may be a factor in the

production of insulin resistance. It was for this reason that histamine in mildly toxic doses was administered frequently for two days to 2 of our patients whose diabetes was controlled. There was no increase of insulin requirement in the 2 cases. These observations are against, but do not eliminate, the possibility that some such substance is a factor in the development of insulin resistance.

The importance of glycogenolysis by the liver in insulin resistance is still a debatable question. Newburgh and Conn¹⁴ have postulated that an excess of fat in the liver is a factor in the glycosuria and hyperglycemia in cases of "fat diabetes." Soskin⁴ has suggested that there is a greater glycogenolysis by the liver in insulin resistance. That a fatty liver was not a factor in insulin resistance in depancreatized dogs was shown by Greene, David and Johnston.¹⁰ Soskin has attributed the glycogenolysis to an abnormal mechanism produced by an increase of amylase. Work recently completed in Gibson's¹⁵ laboratory, however, failed to show any relationship between the blood amylase and the insulin requirement. In addition, one case of mumps pancreatitis in which the blood amylase was greatly increased failed to show hyperglycemia, glycosuria or decreased sensitivity to insulin.

It is difficult to evaluate the role played by the anterior lobe of the pituitary gland in alterations of insulin sensitivity. From the work of Young⁷ and of Best and his co-workers⁸ the action of the pituitary is on the pancreas. The production of insulin resistance in depancreatized dogs¹⁰ casts some doubt on the role played by the anterior pituitary in insulin resistance of toxemias. The roles that are played by the liver, the pituitary, the adrenals and the muscles in the production of decreased sensitivity to insulin are yet to be established.

There is much to be learned regarding the mechanism of insulin resistance which occurs during infection in diabetes mellitus. Regardless of the mechanism there are a few pertinent observations worthy of note. Insulin resistance does not develop in all cases of diabetes mellitus during an infection. It may occur during one infection and not appear during another comparable toxemia. Insulin resistance is more likely to be developed by patients with less severe diabetes than by those with more severe diabetes. As a rule, however, those patients who develop extreme insulin resistance with one infection will also develop it with subsequent infections or fevers.

SUMMARY

The occurrence of insulin resistance has been ascertained in patients with diabetes mellitus during infections, idiopathic fever, administration of foreign proteins, fever produced by the cabinet method and administration of histamine and epinephrine.

Insulin resistance did not develop in all cases of infection or fevers or to administration of histamine or epinephrine. Its occurrence was not related to the sex, age, height and duration of the fever or to the apparent toxemia. Insulin resistance appeared to develop more frequently in mild than in severe cases. Different theories have been advocated to explain this phenomenon.

ABSTRACT OF DISCUSSION

DR. HOWARD F. ROOR, Boston. As the authors say, many different conditions may explain insulin resistance. The occurrence of insulin resistance calls attention to the need of further diagnostic study. Insulin resistance does not develop in all cases during infection. Actually, severe pyogenic infection some times lasts a long time, resulting even in death, and yet insulin resistance not only is absent but the patient, who previously required a large amount of insulin, may become during the last stages of his severe infection sugar free, with normal blood sugar, requiring no insulin. Dr. Vally Menkin of the Harvard Medical School has shown experimentally in diabetic animals that with pleural exudates for example, there is a great excess in proteinolysis, so that the fluids in the affected area contain an excessive amount of amino acid nitrogen. Therefore the rise in blood sugar and the excessive glycosuria may be due to diffusion of dextrose from this area of increased protein breakdown. In a group with infection seen at the Deaconess Hospital resistance to insulin has been associated with allergy to insulin. A patient who, in a previous admission, had a mild diabetes with only temporary use of insulin returned with psoriasis. She required 80 to 90 units and had generalized urticaria whenever insulin was given. She was skin sensitive to the insulin molecule, but also in her blood serum specific precipitins to insulin were demonstrable. Her sensitization decreased and disappeared in the course of some months' time. Another young man, whose blood formerly showed no precipitin to insulin, developed precipitins to insulin and urticaria during the course of record of the lung. A third patient had had diabetes and asthma for many years. With the development of a slight attack of pneumonia, she became comatose and required 140 units. These cases justify the hypothesis that, in the presence of diabetes, an infection not merely may stimulate the antigenic mechanism in such a way as to produce antibodies to the specific invading organism but may stir up antibodies to insulin itself. This possibility is worthy of future study. Disturbances of glycogen storage and increased glycogenolysis occur in skin disorders and in liver disease with increase in insulin requirement. A woman with jaundice due to a stone in the common bile duct at the time of the operation for the removal of the stone required a thousand units a day, a few days later required none and now, two years later, still requires no insulin.

DR. JAMES A. GRIFFIN, Iowa City. None of our cases showed any evidence of skin sensitivity to insulin. It seems difficult to believe that allergy is the important factor in cases with an infection lasting for four or five days, in which a severe insulin resistance develops. In such cases an insulin requirement of 15 units on a given potential sugar intake may increase to as much as 70 to 180 units for four or five days. Immediately after the fever subsides the insulin requirement decreases rapidly and within a week or ten days returns to the previous level. I can hardly see how allergy would explain that mechanism, but neither can I explain it by any other mechanism, so perhaps allergy is as good as any.

The Greatest Joy—There are a few doctors who are disappointed in their profession. Their lives are busy, full of interest, and now and then exciting. New discoveries concerning the causes of disease, new methods, new drugs are constantly appearing, what was final six months ago has already been discarded. The doctor comes to know much of humanity—much more than does the priest, for in times of dire stress nothing is hidden from him—he sees men stripped of their bravado and women shorn of their blandishments, he may admire the courageous, but it is his greater privilege to comfort the frightened and discouraged. Some take pleasure in unraveling an obscure diagnosis, others in the exciting pursuit of an elusive scientific fact, most in the treatment and recovery of their patients. But the greatest joy of every true physician is to do each task well, "his eyes look still upon the pattern of the thing that he maketh, he setteth his mind to finish his work, and watcheth to polish it perfectly"—Irving, Frederick C. Safe Deliverance, Boston, Houghton Mifflin Company, 1942.

MANAGEMENT OF MALE PUBESCENCE

FIRST LIEUT WILLIAM A SCHONFELD

MEDICAL CORPS ARMY OF THE UNITED STATES

The period of pubescence and adolescence in a boy is frequently associated with physical and psychologic problems. Their solution frequently determines the effectiveness and happiness of the adult. It is the obligation of the general practitioner and pediatrician in cooperation with the school authorities, training centers for boys and the family to help solve these problems.¹ This requires an understanding of the mechanisms of pubescence and the ability to recognize and manage adequately their normal and abnormal variations.

MECHANISM OF PUBESCENCE

The development of a person includes a prolonged period of latency in genital growth called prepubesence (fig 1 A to B). During this time the testes do not grow but are maintained in this state of latency through the action of subthreshold amounts of hypophyseal gonadotropic hormones.² During the second decade of life the anterior hypophysis through increased secretion in the quantity of gonadotropic hormones stimulates the interstitial cells of the testes to produce androgenic hormones. These in association with other factors of maturation induce rapid growth and development of the penis, prostate, seminal vesicles, larynx, hair follicles and epiphysis. This period of rapid genital growth is called pubescence² (fig 1 B to C). The point in development when the testes have matured adequately to produce spermatozoa and the individual is capable of procreating is called puberty (C). Postpubescence or adolescence (C-D) follows this, with continued development of the primary and secondary sex characteristics to full maturity (D).

RANGE OF VARIATION

In view of the complexity of the process of growth and maturation it is not surprising to find great variations in normal boys⁴ as to the age of onset of pubes-

cence, the rate of development and the ultimate size of the genitalia. To determine the range of this variation I correlated the measurements of the penis and testes⁵ with the degree of maturation of the secondary sex characteristics in about 1,500 males selected at random.

These subjects were then arbitrarily subdivided into six stages of development and maturation (fig 2). The first stage included all the prepubescents and the sixth the adolescents and physically matured individuals, while the intervening stages included all the boys during pubescence. The qualifying criterion for the second stage was the beginning of active growth of the testes and penis but no pubic hair, while the third, fourth and fifth stages included respectively the three stages of pubic hair development described by Crampton.⁶ In each stage I noted the range of size of the penis and testes as well as the associated secondary sex characteristics.

On the basis of this classification, the age frequency distributions were plotted for the 1,500 normal boys and men ranging in age from 1 day to 25 years (fig 3). This chart indicates the decided variation as to physiologic development at each age. It illustrates that pubescence (stage 2) may normally begin at any age from 10 to 16, with isolated cases beginning even

Fig 1—Phases of individual development. A to B prepubesence, B to C pubescence, C to D postpubescence (adolescence). Point C puberty, point D maturity.

later, and the knowledge of the median or average age of onset is of no significance.⁶

Cognizance of these variations of the normal⁷ is one of the most important factors in the management of the male pubescent. By far the greatest number of prepubescents who are commonly regarded as endocrine problems will develop into normal adults,⁸ whether the problem relates to the size of the genitalia, obesity or growth. This development is best achieved by wholesome surroundings among well adjusted adults, an adequately controlled diet and a well balanced ratio of rest and exercise, depending on the boy's needs.

nology is the management of the obese boy.⁹ Since the distribution of fat in these boys resembles that found in women and adult eunuchs, the physician is inclined to make a diagnosis of obesity due to hypogonadism particularly since the genitalia appear small. They fail to realize that this type of obesity is not at all abnormal in boys having a pyknic or predominantly endomorphic somatotype.¹⁰

The apparent hypogonadism is due to the fact that the penis is usually embedded in suprapubic fat. When the fat pad is pushed back (figs 4 and 5) and the penis and testes are measured, it is evident that the genitalia are within the range of normal when compared to previously established standards¹¹ and that there is no delay in onset of pubescence.¹² Since there is no genital dystrophy, the diagnosis which is so frequently made of adiposogenital dystrophy of Frohlich's type is entirely unwarranted. With the advent of puberty,

ments with a relatively high proportion of protein and supplementary vitamins and reduction of salts and fluids to a minimum. Although myxedema is uncommon, thyroid may be given along with the proteins to accelerate the basal metabolism. To be effective, desiccated thyroid must be given in the highest dose tolerated,¹⁴ which is just below the toxic level for the individual. In addition amphetamine sulfate may be used in 5 to 10 mg doses morning and afternoon to dull insatiable appetites.¹⁵

RATIONAL OF ENDOCRINE THERAPY

The literature has created a great deal of confusion as to the indications, limitations and contraindications of the many commercially available potent endocrine products.¹⁶ I shall attempt to clarify this situation by presenting a rational approach to the treatment of the problems associated with pubescence based on our controlled experiences in the endocrine clinics of Columbia-Presbyterian Medical Center and Morrisania City Hospital in a series of more than 750 cases.

There are two main groups of endocrine substances used for the male, the gonad stimulating or gonadotropic substances and the gonad substituting or androgenic substances. The gonadotropic substances are commercially available from three sources: the anterior hypophyseal gonadotropins, extracts of the anterior pituitary gland of animals, chorionic gonadotropins of pregnant mare serum, and chorionic gonadotropins of human pregnancy urine. The relative effectiveness of these products depends on the total concentration of gonadotropic hormones present and the relative amounts of gametogenic and interstitial cell stimulating hormones which they contain.

Extracts of human pregnancy urine have been used extensively because of their high concentration of interstitial cell stimulating chorionic gonadotropins to stimulate the testes to produce androgens. The androgens, in turn, are now commercially available as testosterone propionate, in 10 mg and 25 mg ampules for intramuscular injection, methyl testosterone for oral administration in 10 mg tablets and testosterone pellets to be used as implants. All three are also available as injections. Their action is identical to the androgens produced by the testes, namely to stimulate the accessory reproductive organs and secondary sex characteristics. As yet there is no known endocrine product capable of initiating spermatogenesis.

The physiologic action of both of these types of hormones is the induction of pubescence. The chorionic gonadotropins of human pregnancy urine act by stimulating the interstitial cells of the testes while the androgens act through substitution for the mature testis. This I believe is the basis for all endocrine therapy in the prepubescent whether it is directed

most of these boys grow taller and slimmer¹⁷ although I believe they usually maintain their characteristic somatotype through life.

Thus, the treatment limits itself to a slimming regimen and the formation of new habits of activity and interests. Accordingly, to induce loss of weight¹⁸ the diet should be reduced to the basal caloric require-

against sexual immaturity, eunuchoidism, inadequate or excessive growth lack of testicular descent or merely anxiety as to genital adequacy. The treatment varies only as to the product used, dosage, duration of treatment and stage of pubescence induced (fig 2)

PROGNOSTICATION OF SEXUAL DEVELOPMENT

In the management of the prepubescent his present genital status is of interest only as it reflects the individual's future sexual development, since the actual size of the genitalia is of physiologic significance only after pubescence. In the prepubescent one is concerned with the ability to respond to future stimulation and the probability of the anterior hypophysis to initiate this stimulation in due time.

I use various indirect methods to evaluate this prognosis, since hormone assays¹⁷ were found to be of no aid in the prepubescent. Measurements of the penis and testes are of value to differentiate normal boys with apparently small genitalia from those with actual genital hypoplasia. It is to be remembered that the testes are normally maintained during prepubescence in a latent state by the action of minimal amounts of gonadotropic substances from the anterior hypophysis. Any disturbance of this function may cause an aplasia of the testes³ similar to that found in primary testicular

response is expressed as an increase in the circulating androgens¹⁸ and is clinically manifested by congestion and enlargement of the penis and subsequently the prostate. This response has often been misinterpreted in the literature as a therapeutic achievement.

Usually 500 to 750 international units three times each week of a proved potent batch of chorionic gonadotropin of human pregnancy urine is adequate to stimulate the testis but if no response is noted in two or three weeks the dose is increased to 1,500 international units three to five times each week for two or three weeks more. Evidence of response warrants the assertion that the boy has at least one normal testis and probably adequate anterior hypophysial function, so that he will have spontaneous pubescence in due time if there is no abnormal change in his status.

Fig 4—Appearance of a prepubertal obese boy with apparent hypoplasia of the genitalia

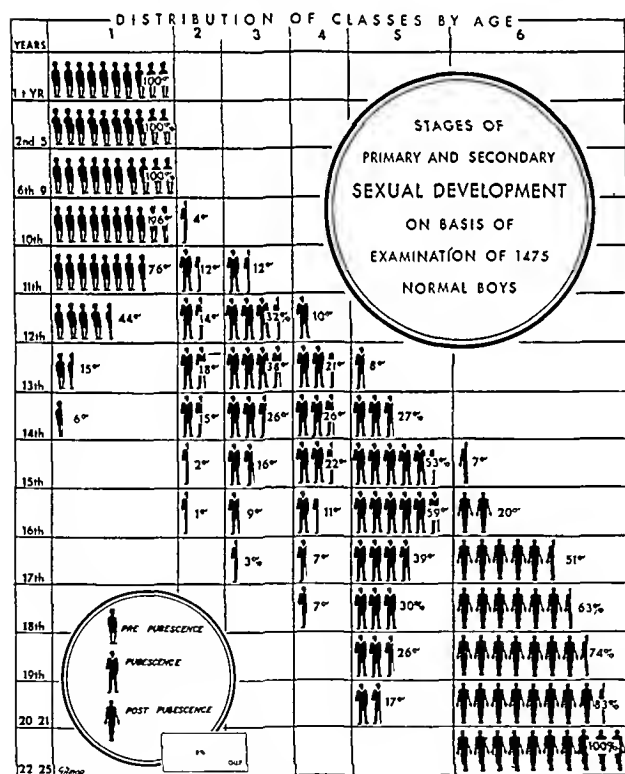

Fig 3—Age frequency distribution of the six stages of development and maturation. Each figure represents 10 per cent of total in each age group.

hypoplasia. Thus testing the responsiveness of the testes to large doses of chorionic gonadotropins of human pregnancy urine would help evaluate both gonadal and hypophysial factors in pubescence. This

CRYPTORCHISM, DELAYED PUBERTY AND EUNUCHOIDISM

In the prepubescent it is frequently difficult to differentiate bilateral cryptorchism or delayed puberty from eunuchoidism. Thus I find it necessary at times to utilize the prognosticating therapeutic test as a criterion for differential diagnosis.

Cryptorchism has been discussed so frequently in the literature¹⁹ that I shall not review my experience except to stress the fact that a diagnosis should not be made until after thorough and repeated examinations, as illustrated in figures 6 and 7. I have often noted that in the presence of a hyperactive cremasteric reflex the testis may ascend through the open inguinal canal or under the fascia. It is important to differentiate

these patients with migratory cryptorchism who require no treatment except in the presence of torsion, from those boys with an actually undescended or ectopic testis.²⁰ Even if both testes are undescended, the abnormal positions do not interfere with the functioning of the interstitial tissue,²¹ so that pubescence develops normally. However, the seminiferous tubules usually fail to mature and degenerate with the advent of pubescence.

In eunuchoidism there is a complete aplasia of the testes so that pubescence never develops spontaneously. Once a diagnosis of eunuchoidism²² is established an attempt should be made to differentiate patients with intracranial lesions and primary hypophysial disturbances from those with primary testicular hypoplasia as a result of a congenital defect or disturbance of testicular circulation caused by torsion or surgery.

Pubescence fails to develop in many patients with hypophysial disturbances²³ as a result of intrasellar

Fig 5—Appearance of genitalia of boy shown in figure 4. To evaluate the genitalia suprapubic fat pad is pushed back.

and of extrasellar pathologic conditions. The anterior lobe of the hypophysis is directly involved in eosinophilic tumors with gigantism, in chromophobe or basophilic adenomas or as a result of congenital aplasia of the gland as in hypophysial dwarfism (atrophic or Loran-Levi). However, inflammatory or degenerative processes of the base of the brain or skull or a suprasellar neoplasm, such as a craniopharyngioma,²⁴ may through pressure directly on the hypophysis or through a disturbance of its circulation or neurotropic fibers also create secondary eunuchoidism.

24 Rathke pouch tumor or hypophysial stalk tumor.

In primary eunuchoidism, the goal of treatment in children as in adults is the development of primary and secondary sex characteristics with androgens,²⁵ the best guide to dosage being the child's response. Start with 10 mg of testosterone propionate by intramuscular injection three times each week or give 30 mg of methyl testosterone daily by mouth or insert 150 mg pellets of testosterone subcutaneously, increasing as indicated to 25 mg of testosterone propionate hypodermically three times each week to induce pubescence. When development reaches the maximum for the individual a maintenance dose must be established and continued through life, otherwise regression will take place.

In secondary eunuchoidism however the treatment should first be directed to eliminate if possible, the primary pathologic process by means of neurologic surgery or radiation therapy. If this fails to allow pubescence to develop or if the etiologic process cannot be eliminated then only should androgens be used to induce pubescence.

ADIPOGENITAL DYSTROPHY, OR FROHLICH'S SYNDROME

The term Frohlich's syndrome has been used so frequently as a diagnosis of obesity in childhood when associated with only apparent hypogonadism that its true significance has been lost.²⁶ The use of this term should be limited to cases of secondary eunuchoidism associated with obesity as a result of a craniopharyngioma or an inflammation or degenerative lesion involving both the hypothalamus and the hypophysis. Before labeling a boy as having Frohlich's syndrome one should consider carefully whether he actually has adiposogenital dystrophy with a bad prognosis or merely prepubertal obesity with normal genitalia and an excellent prognosis. The treatment of Frohlich's syndrome involves the removal of the primary pathologic process if possible and induction of pubescence with androgens. A slimming regimen is also instituted for the obesity.

PROBLEMS OF GROWTH IN HEIGHT

Although a great deal has been written about the diagnosis, pathology and treatment of the abnormalities of growth a conclusive understanding of the problem is not available. The one approach that I consider of primary importance in the determination of the prognosis of a boy with idiopathic or hypophysial dwarfism is to evaluate his genital status.

Since the anterior lobe of the pituitary gland controls both growth and gonadal development it is readily understood that aplasia of this gland would at times

result in eunuchoidal hypophysial dwarfism. The other forms of intracranial disorder previously discussed which might give rise to hypophysial eunuchoidism are also associated with short stature except in cases of eosinophilic tumors which through their excessive secretion of growth factors result in gigantism.

In the normal boy the continued secretion of hypophysial growth factors stimulates progressive growth until the onset of pubescence. At this time probably as a result of an increase in androgens the epiphyses receive an extra stimulus resulting in a prepubertal spurt of growth followed by fusion of the epiphyses and cessation of growth. This is associated with the further maturation of the gonads and epiphyses.

However in primary eunuchoidism the absence of testicular development prevents fusion of the epiphyses and allows continued action of the growth factors to stimulate long bone growth resulting in a tall eunuchoid. In cases of precocious puberty however the premature maturation of the gonads creates an early pubescent spurt of growth and excessive height for the child's age which is then followed by early closure of the epiphyses and ultimate deficiency in height.

I have presented this theoretical explanation of the various problems related to idiopathic and hypophysial-gonadal dwarfism in order to create a better understanding of the rationale of treatment as I see it. When deficiency of growth is associated with eunuchoidism as

growth². However usually deficiency in growth during prepubescence is not associated with eunuchoidism, although frequently there is a delay in the age of onset of pubescence to the upper limits of normal. In cases of short normal boys I have tried the various commercially available growth factors and found them to be of no value. I have thus reverted to the use of large doses of thyroid adequate diet with supplementary vitamins fresh air and exercise to stimulate the patient's maximum growth.²⁵

However in isolated instances of prepubescent boys ranging in age from 12 to 18 years I have used large doses of androgens over a period of four to eight weeks, inducing the earliest evidence of pubescence (class 1, fig 2) and the frequently associated spurt of growth.²⁶ Treatment would then be stopped for three to six months to allow regression of the genital response. This course would be repeated in the hope that a series of two or three such growth spurts would be greater than the one growth spurt which the boy would have had spontaneously. I do not generally recommend this form of treatment as it is still experimental. The danger is that the genital maturation will be carried too far, which would induce the same situation as in precocious puberty, namely a premature closure of the epiphyses and cessation of growth.²⁶

Fig 7—Method of examination for position of testes in cryptorchidism. The diagnosis undescended testis should never be made until repeated examinations fail to bring it into the scrotum.

Fig 6—Methods of examination for position of testes. A apply pressure over external inguinal ring before palpating the scrotum to prevent retraction of the testes. B apply suction to stretch the scrotum and gubernaculum. C apply local heat for relaxation. D institute hyperextension.

proved by the fact that the boy has no genital response to large doses of chorionic gonadotropins of human pregnancy urine as previously described, the treatment is directed toward the induction of pubescence with androgens. This is usually associated with a spurt of

ACNE

Acne occurs as a result of the increased activity of the sebaceous glands associated with hair follicle development²⁷ during normal pubescence. Nevertheless it causes many pubescents a great deal of anxiety. Every endocrine substance has been used for acne but I have found none of them to be effective. Local treatment seems to be the only therapy of value. If boys are taught to use a face brush and tincture of green soap early in pubescence severe acne can be avoided. Once it is present and secondary infection has ensued the most effective treatment seems to be 10 per cent salicylic acid ointment.

GYNecomastia

Normal boys frequently have some mammary tissue response during pubescence, varying from a small nodule to diffuse hypertrophy of one or both breasts, which subsides at puberty.³¹ In those cases in which the enlarged breasts persist beyond puberty we have tried every form of endocrine therapy without avail. The treatment of choice for this condition is plastic surgery, except in eunuchoids, in whom androgenic therapy seems to help when the degree of gynecomastia is mild. Dr Jerome P. Webster has perfected a mastectomy through a circumareolar incision which leaves no perceptible postoperative scar. This operation has been ideal to obviate the psychic trauma so often caused by enlarged breasts.

PSYCHOGENIC PROBLEMS

The psychologic makeup of a boy must always be taken into consideration in the management of all problems related to pubescence. In using gonadotropins or androgens care should be taken not to allow the genital development to advance beyond the normal range for the boy's age and his ability to handle the ensuing emotional problems.³ This is particularly true in the treatment of psychoneurotic and mentally retarded boys. However, the induction of pubescence in young eunuchoids obviates the many psychogenic problems associated with this condition.

If anxieties exist as to genital development, it is not enough to state that the boy's penis is normal for his age but he must accept it as being normal. I have thus at times induced early pubescence (stage 2) in perfectly normal young boys with apparent genital hypoplasia to inflate the boy's own ego if psychotherapy alone has failed.

CONCLUSION

Chorionic gonadotropins and androgens are potent drugs capable of modifying both the physical and the emotional development of the male pubescent. The judicious use of these substances requires an understanding of the physiologic mechanisms of pubescence and the action of the various substances.

A great deal of therapeutic confusion has been created in the literature by the failure to appreciate the range of normal variation of genital size, age of onset of pubescence and the characteristics of growth of the various types of body configurations (somatotypes). Many of these normal boys have been subjected to prolonged endocrine treatment with induction of pubescence, and their normal development is fallaciously attributed to endocrine therapy. An accurate evaluation of the existing status and future prognosis is essential for the proper management of the prepubescent and pubescent boy.

COMMENT

In this presentation, the developmental aspects of pubescence were stressed. Criteria were presented for the arbitrary division of development and maturation

into six stages on the basis of genital measurements and associated secondary sex characteristics, and the age frequency distribution was plotted for about 1,500 boys under observation. Attention was drawn to the prolonged phase of genital latency during prepubescence and the appreciable variation in age of the onset of pubescence. These often create a problem of differentiating the normal prepubescent from the eunuchoid.

A test to prognosticate in prepubescence whether a boy will have spontaneous pubescence is based on the ability of the testes to respond to stimulation by chorionic gonadotropins of human pregnancy urine.

Induction of pubescence is the basis of nearly all endocrine therapy in this age group. The treatment varies only as to whether such endocrine products are used which stimulate the interstitial tissue of the testes to function (gonadotropins) or those which substitute for the hormones ordinarily secreted by the mature testes (androgens). The stage of pubescence to be induced also varies.

Obesity and growth should be considered in their correlation with genital development and pubescence. The criteria used differentiated in the first group the prepubertal boy with obesity from the boy with true Frohlich syndrome and in the latter group the short normal from the hypoplastic dwarf.

THE HOSPITAL AND THE SYPHILIS
PROBLEM IN PROSPECTIVE
BLOOD DONORS

WILLIAM W. FRYE, PH.D., M.D.

MAX I. KELLER, M.D.

AND

RUDOLPH H. KAMPMIETTER, M.D.

NASHVILLE, TENN.

In the United States each year a large number of persons volunteer as blood donors at the request of friends and relatives. During the present emergency the American Red Cross is collecting large quantities of blood from voluntary donors. Most of them young adults, these volunteers consider themselves in good health and free of disease. Many of them however are found on serologic examination by one of the standard methods to have a positive reaction for syphilis. Of 19,141 tests performed on prospective blood donors over a period of about five and one-half years at the Vanderbilt University Hospital 33 per cent of the donors were found to give a positive or a doubtful serologic reaction for syphilis on one examination.¹ While a single positive or doubtful blood test is not sufficient evidence to make a diagnosis of syphilis, nevertheless the possibility that these persons may have syphilis must be considered. Many of them may go on for years without having the disease recognized unless some one notifies them of the serologic results.

This paper presents the findings of a study designed to find out what is being done about the donors who have a positive or doubtful serologic reaction for syphilis. Hospitals accepting persons as blood donors should take the responsibility of informing them if the

preliminary examination indicates the presence of any disease. To determine how many hospitals did assume this responsibility and in what manner questionnaires were sent to the superintendent of a geographically representative group of hospitals in the United States. The questionnaire prepared sought to obtain information on the following points:

1. Do you operate your own serologic laboratory for the diagnosis of syphilis?
2. If you do not operate your own serologic laboratory, where are tests performed for patients in your hospital?
3. Do you perform routine serologic tests for syphilis on all blood donors for transfusions in your hospital?
4. Do you have a procedure by which donors are notified if they have a positive reaction?
5. Who is responsible for notification of the donor?
6. Is the donor notified by interview or letter?
7. To what agency do you report positive reactions of donors?

The questionnaire was signed by the superintendent of Vanderbilt University Hospital and sent to 800 hospitals chosen from "The Transactions of the American Hospital Association for 1940." In all 603 questionnaires were returned, representing hospitals from forty-seven of the forty-eight states.

INFORMATION OBTAINED BY QUESTIONNAIRE

Serologic Laboratory Facilities According to Geographic Region.—The number and percentage of hospitals operating a serologic laboratory and testing donors for syphilis is shown in table 1. The United States was divided into eight geographic regions according to the classification of the U. S. Bureau of Census. Of the 603 hospitals, 478 operated their own serologic laboratory and 125 used public health or private laboratories. In the hospitals operating their own laboratories, 4 per cent stated that they did not test donors for syphilis. In the group of hospitals not operating a serologic

donors is presented in table 2. The percentage of hospitals not operating their own serologic laboratory and those not testing donors for syphilis is much higher in hospitals of less than 200 beds. The total not testing donors was 16.3 per cent in hospitals of 100 beds or less and 9.2 per cent in those with 100 to 199 beds.

TABLE 2—Number and Percentage of Hospitals Operating a Serologic Laboratory and Testing Donors for Syphilis According to Size

Size of Hospital (Number Beds)	Total Hospitals	Operating Serologic Laboratory		Not Operating Serologic Laboratory		Percentage Not Testing Donors for Syphilis	
		Total	Not Testing Donors for Syphilis	Total	Not Testing Donors for Syphilis	Operating Serologic Laboratory	Not Operating Serologic Laboratory

laboratory, 16.1 per cent of the hospitals of 500 beds or more were not performing routine serologic tests for syphilis on blood donors. As would be expected, the percentage not testing donors was uniformly higher in all groups that did not have their own serologic laboratory than in those with a laboratory, except in the group of hospitals of 300 to 499 beds.

Serologic Laboratory Facilities According to Type of Hospital Control.—The same kind of analysis with respect to the type of administrative control shows (table 3) that the denominational hospitals had the highest percentage (10.1 per cent) not testing donors for syphilis. Only 1 of the municipal hospitals did not examine donors, and this was a hospital which operated its own serologic laboratory. The percentage not testing donors for syphilis is highest in those hospitals not operating their own serologic laboratory.

Responsibility for Notification of Positive Donors.—As pointed out previously, the hospital may require examination of prospective blood donors for syphilis, but it is also essential that they notify these donors when positive or doubtful serologic results are obtained.

The rest of this discussion deals with the methods by which the hospitals performing tests on donors fulfill their responsibility of notification.

Information regarding the responsibility for the notification of donors in hospitals examining them for syphilis is shown in tables 4 and 5. Considering the group as a whole, 9.4 per cent stated that they did not notify donors when the test gave a positive result. The private or attending physician was stated to be responsible for notifying the donor in 38.3 per cent. In about one fourth the house officer was responsible, while the pathologist or laboratory director handled the notification in approximately 14 per cent. Less than 5 per cent of the hospitals delegated the responsibility to the social service staff or to the health department. There was a fairly large proportion of hospitals which named some other agency or person responsible for notification. These included the admitting officer, the private laboratories, the superintendent's office, and other hospital personnel.

TABLE 1—Number and Percentage of Hospitals Operating a Serologic Laboratory and Testing Donors for Syphilis According to Geographic Region

Geographic Region	Total Hospitals	Operating Serologic Laboratory		Not Operating Serologic Laboratory		Percentage Not Testing Donors for Syphilis	
		Total	Not Testing Donors for Syphilis	Total	Not Testing Donors for Syphilis	Operating Serologic Laboratory	Not Operating Serologic Laboratory

laboratory, 16.1 per cent did not have a blood test for syphilis performed. Altogether 6.5 per cent stated that they were not testing blood donors for syphilis. This percentage is highest in the West North Central, West South Central and Mountain areas.

Serologic Laboratory Facilities According to Size of the Hospital.—The variation according to the size of the hospital in the proportion testing and those not testing

GYNecomastia

Normal boys frequently have some mammary tissue response during pubescence, varying from a small nodule to diffuse hypertrophy of one or both breasts, which subsides at puberty.³¹ In those cases in which the enlarged breasts persist beyond puberty we have tried every form of endocrine therapy without avail. The treatment of choice for this condition is plastic surgery, except in eunuchoids, in whom androgenic therapy seems to help when the degree of gynecomastia is mild. Dr. Jerome P. Webster has perfected a mastectomy through a circumareolar incision which leaves no perceptible postoperative scar. This operation has been ideal to obviate the psychic trauma so often caused by enlarged breasts.

PSYCHOCENIC PROBLEMS

The psychological makeup of a boy must always be taken into consideration in the management of all problems related to pubescence.³² In using gonadotropins or androgens care should be taken not to allow the genital development to advance beyond the normal range for the boy's age and his ability to handle the ensuing emotional problems.³³ This is particularly true in the treatment of psychoneurotic and mentally retarded boys. However, the induction of pubescence in young eunuchoids obviates the many psychogenic problems associated with this condition.

If anxieties exist as to genital development it is not enough to state that the boy's penis is normal for his age but he must accept it as being normal. I have thus at times induced early pubescence (stage 2) in perfectly normal young boys with apparent genital hypoplasia to inflate the boy's own ego if psychotherapy alone has failed.

CONCLUSION

Chorionic gonadotropins and androgens are potent drugs capable of modifying both the physical and the emotional development of the male pubescent. The judicious use of these substances requires an understanding of the physiologic mechanisms of pubescence and the action of the various substances.

A great deal of therapeutic confusion has been created in the literature by the failure to appreciate the range of normal variation of genital size, age of onset of pubescence and the characteristics of growth of the various types of body configurations (somatotypes). Many of these normal boys have been subjected to prolonged endocrine treatment with induction of pubescence, and their normal development is fallaciously attributed to endocrine therapy. An accurate evaluation of the existing status and future prognosis is essential for the proper management of the prepubescent and pubescent boy.

COMMENT

In this presentation, the developmental aspects of pubescence were stressed. Criteria were presented for the arbitrary division of development and maturation

into six stages on the basis of genital measurements and associated secondary sex characteristics, and the age frequency distribution was plotted for about 1,500 boys under observation. Attention was drawn to the prolonged phase of genital latency during prepubescence and the appreciable variation in age of the onset of pubescence. These often create a problem of differentiating the normal prepubescent from the eunuchoid.

A test to prognosticate in prepubescence whether a boy will have spontaneous pubescence is based on the ability of the testes to respond to stimulation by chorionic gonadotropins of human pregnancy urine.

Induction of pubescence is the basis of nearly all endocrine therapy in this age group. The treatment varies only as to whether such endocrine products are used which stimulate the interstitial tissue of the testes to function (gonadotropins) or those which substitute for the hormones ordinarily secreted by the mature testes (androgens). The stage of pubescence to be induced also varies.

Obesity and growth should be considered in their correlation with genital development and pubescence. The criteria used differentiated in the first group the prepubertal boy with obesity from the boy with true Frohlich syndrome and in the latter group the short normal from the hypophyseal dwarf.

THE HOSPITAL AND THE SYPHILIS
PROBLEM IN PROSPECTIVE
BLOOD DONORS

WILLIAM W. FRYE, PH.D., M.D.

ALAN L. KELLER, M.D.

AND

RUDOLPH H. KAMPMEIER, M.D.

NASHVILLE, TENN.

In the United States each year a large number of persons volunteer as blood donors at the request of friends and relatives. During the present emergency the American Red Cross is collecting large quantities of blood from voluntary donors. Most of them young adults these volunteers consider themselves in good health and free of disease. Many of them however are found on serologic examination by one of the standard methods to have a positive reaction for syphilis. Of 19,141 tests performed on prospective blood donors over a period of about five and one-half years at the Vanderbilt University Hospital 33 per cent of the donors were found to give a positive or a doubtful serologic reaction for syphilis on one examination.¹ While a single positive or doubtful blood test is not sufficient evidence to make a diagnosis of syphilis, nevertheless the possibility that these persons may have syphilis must be considered. Many of them may go on for years without having the disease recognized unless some one notifies them of the serologic results.

This paper presents the findings of a study designed to find out what is being done about the donors who have a positive or doubtful serologic reaction for syphilis. Hospitals accepting persons as blood donors should take the responsibility of informing them if the

preliminary examination indicates the presence of any disease. To determine how many hospitals did assume this responsibility and in what manner questionnaires were sent to the superintendent of a geographically representative group of hospitals in the United States. The questionnaire prepared sought to obtain information on the following points:

1. Do you operate your own serologic laboratory for the diagnosis of syphilis?
2. If you do not operate your own serologic laboratory, where are tests performed for patients in your hospital?
3. Do you perform routine serologic tests for syphilis on all blood donors for transfusions in your hospital?
4. Do you have a procedure by which donors are notified if they have a positive reaction?
5. Who is responsible for notification of the donor?
6. Is the donor notified by interview or letter?
7. To what agency do you report positive reactions of donors?

The questionnaire was signed by the superintendent of Vanderbilt University Hospital and sent to 800 hospitals chosen from "The Transactions of the American Hospital Association for 1940." In all 603 questionnaires were returned, representing hospitals from forty-seven of the forty-eight states.

INFORMATION OBTAINED BY QUESTIONNAIRE

Serologic Laboratory Facilities According to Geographic Region.—The number and percentage of hospitals operating a serologic laboratory and testing donors for syphilis is shown in table 1. The United States was divided into eight geographic regions according to the classification of the U. S. Bureau of Census. Of the 603 hospitals, 478 operated their own serologic laboratory and 125 used public health or private laboratories. In the hospitals operating their own laboratories, 4 per cent stated that they did not test donors for syphilis. In the group of hospitals not operating a serologic

Total	603	478	19	125	20	40	161	65

Only 13 per cent of the hospitals of 500 beds or more were not performing routine serologic tests for syphilis on blood donors. As would be expected, the percentage not testing donors was uniformly higher in all groups that did not have their own serologic laboratory than in those with a laboratory, except in the group of hospitals of 300 to 499 beds.

Serologic Laboratory Facilities According to Type of Hospital Control.—The same kind of analysis with respect to the type of administrative control shows (table 3) that the denominational hospitals had the highest percentage (101 per cent) not testing donors for syphilis. Only 1 of the municipal hospitals did not examine donors, and this was a hospital which operated its own serologic laboratory. The percentage not testing donors for syphilis is highest in those hospitals not operating their own serologic laboratory.

Responsibility for Notification of Positive Donors.—As pointed out previously, the hospital may require examination of prospective blood donors for syphilis, but it is also essential that they notify these donors when positive or doubtful serologic results are obtained.

The rest of this discussion deals with the methods by which the hospitals performing tests on donors fulfil their responsibility of notification.

Information regarding the responsibility for the notification of donors in hospitals examining them for syphilis is shown in tables 4 and 5. Considering the group as a whole 94 per cent stated that they did not notify donors when the test gave a positive result. The private or attending physician was stated to be responsible for notifying the donor in 38.3 per cent. In about one fourth the house officer was responsible while the pathologist or laboratory director handled the notification in approximately 14 per cent. Less than 5 per cent of the hospitals delegated the responsibility to the social service staff or to the health department. There was a fairly large proportion of hospitals which named some other agency or person responsible for notification. These included the admitting officer, the private laboratories, the superintendent's office and other hospital personnel.

laboratory, 161 per cent did not have a blood test for syphilis performed. Altogether 65 per cent stated that they were not testing blood donors for syphilis. This percentage is highest in the West North Central, West South Central and Mountain areas.

Serologic Laboratory Facilities According to Size of the Hospital.—The variation according to the size of the hospital in the proportion testing and those not testing

When broken down according to size of hospital, table 4 shows that in hospitals of 100 beds or less and in the group of 500 beds or more the percentage which did not notify the donors having positive or doubtful serologic reactions was about 6. This percentage increased to approximately 10 in hospitals of

Other than municipal

from 200 to 500 beds. The percentage of hospitals relying on the private or attending physician for notification decreased with the size of the hospital, being lowest in hospitals with 500 beds or more. The hospitals depending on social service personnel for notification were almost all in the group with 200 beds or more and were probably all teaching hospitals or connected with a medical school.

Table 5 shows the influence of the type of administrative control on the responsibility for notification. Almost 12 per cent of the denominational hospitals failed in any way to notify donors with a positive serologic reaction. The corresponding percentage for private hospitals was almost as high, while for governmental hospitals it dropped to 7.9 per cent. Almost

TABLE 4—Responsibility for Notification of Donors, According to Size of Hospital*

* Some hospital named more than one plan for notification of donors; therefore the percentages may add to more than 100.

all the municipal hospitals examining donors notified them in some way, only 3.8 per cent failing to do so. It is seen that 54 per cent of the denominational and 39.4 per cent of the private hospitals placed the responsibility for notification in the hands of the private or attending physician. There was not a great deal of variation with type of control in the percentage of

hospitals using the house officers to notify donors. The same is true of hospitals utilizing the pathologist or laboratory director or the health department. In the municipal hospitals 13.2 per cent stated that the social service personnel notified donors.

Methods Used to Notify Positive Donors—Tables 6 and 7 show the methods used to notify donors with positive reactions. There was no definite plan or system for notifying them in 12.5 per cent of the hospitals. Approximately half of the hospitals stated that these donors were informed of the serologic findings by personal interview. The private or attending physician was listed as the means of notification in 23.5 per cent of the hospitals, which was interpreted as meaning that the physician was left with the entire responsibility. Only 7.8 per cent notified by letter and 7.6 per cent by letter and interview. The group using other methods included those stating that the donor was notified by telephone or by other members of the family.

The effect of the size of the hospital on the method of notification is shown in table 6. The percentage of hospitals having no method of notifying donors decreased with increasing size of the hospital, with the

* Some hospital named more than one plan for notification of donors; therefore the percentages may add to more than 100.

exception of hospitals with 300 to 499 beds. Smaller hospitals or those with less than 200 beds leave the problem of notification in the hands of the private physician, while larger hospitals seem to rely more on the interview or letter or both as a means of notification of donors.

Table 7 shows the methods used to notify donors according to the type of administrative control. The private and denominational hospitals show the highest percentage having no system for notification of donors. When they do have a system they favor the interview as the method of notification, although denominational hospitals depend somewhat more on the private or attending physician.

The municipal and governmental hospitals use the same methods for notifying donors. Only about 7 per cent had no method for notification and approximately one half of this group of hospitals notify by personal interview. Since the number of private patients are fewer in this group of hospitals, the private or attending physician was listed as the means of notification in only 5.8 per cent of the municipal and 13.8 per cent of the governmental hospitals. In 25 per cent of the municipal hospitals letters were used and in 11.5 per cent both letter and interview.

COMMENT

This study shows that 65 per cent of the 603 hospitals from which replies to the questionnaire were received did not test blood donors for syphilis before their blood was used. Of the hospitals testing donors for syphilis 12.5 per cent had no method for notifying these donors when they were found to have a positive or doubtful serologic reaction. Of the 603 hospitals, then 16.2 per cent either did not examine donors for syphilis or did not notify them when the serologic test was found to be positive.

It is impossible to determine how many persons are examined each year as prospective blood donors. There is no doubt that several thousand of these donors will have a positive reaction suggesting the presence of syphilis. In a large proportion of cases a blood donor found to have syphilis is not aware of the infection. If these positive donors are not informed of the results of the laboratory tests and if the significance is not explained to them, they may transmit the disease to others or late manifestations of the disease may develop which could have been prevented by treatment. Hospitals, therefore, should develop some system for notification and follow-up of each donor found to have a positive serologic reaction for syphilis.

That most hospitals would attempt to correct this situation if it were called to their attention would seem to be borne out by some of the letters which were returned with the questionnaires. The following letter was received from a hospital connected with a large medical school:

Your questionnaire called to our attention a very definite deficiency in our practice, namely, that we have not been informing blood donors of the findings in connection with Wassermann tests that were made. This deficiency has now been corrected and the member of the house staff who withdraws the blood sample has been made responsible for informing the donor of the result of the Wassermann examination, particularly in cases where findings are positive, and of advising them concerning treatment.

Another letter states:

At the time we received your inquiry we did not do serological tests on donors, but since then we have made it a standard practice.

TABLE 6—Methods Used to Notify Positive Donors According to Size of Hospital

Size of Hospital (Number Beds)	Number of Hospitals	Percentage Having No Method of Notifying Donors	Percentage Notifying by Interview	Percentage Notifying by Private or Attending Physician	Percentage Notifying by Letter	Percentage Notifying by Interview and Letter	Percentage Notifying by Other Methods	Total Percentage
Less than 100	36	20.0	25.7	45.7	5.7	2.9	0.0	100.0
100-199	218	13.2	46.8	39.2	3.4	4.7	0.4	100.0
200-299	149	10.3	55.2	17.9	7.6	6.2	2.8	100.0
300-499	85	16.7	40.5	19.0	9.5	11.9	2.4	100.0
500+	75	6.6	60.0	4.1	23.0	14.9	1.4	100.0
Total	564	12.5	47.1	23.5	7.8	7.6	1.5	100.0

Such letters indicate steps in the right direction. In order, however, for hospitals to have a successful system for notification of donors, the problem must be handled by one person. This person should be a permanent member of the hospital staff and all serologic tests for syphilis on blood donors should be reported to the person responsible for notification.

It has been our experience that a plan which depends on the house staff or the private physician is not satisfactory. A more definite system for notification of donors with positive serologic reactions is necessary as emphasized in a study of serologic reactions for syphilis in blood donors made at Vanderbilt University.

TABLE 7—Methods Used to Notify Positive Donors According to Type of Hospital Control

* Other than municipal.

Hospital in 1937. In July of that year a plan for notification was developed whereby persons who volunteered as blood donors were asked to specify whether or not they wished to be informed of the results of the serologic test in the event of a positive reaction. At the time the specimen of blood was obtained the donor was asked to sign a printed form indicating whether or not he wished to be notified by personal interview or by letter. Duplicate forms were to be made out by the house officer who drew the blood from each donor. This plan failed, since the house officer, owing to lack of time and interest, soon neglected to fill out the forms. During the two and one-half years that this plan was used the house officers were given the entire responsibility for notification, but only very few donors were informed of the result of the test unless a special effort was made on their part to get in touch with the same house officer who drew the blood. Since July 1940 one of us has taken the responsibility for notification of all donors who are found to have a positive or a doubtful serologic reaction for syphilis. All donors are notified by letter or by personal interview. If there is no response to the letter, a visit is made and the need for another blood test is explained to the donor. If the second test gives a positive reaction, the person is referred to his family physician or to a clinic for final diagnosis and treatment. With this plan much better results were obtained.

If hospitals do not have a system for notification of donors, they should be encouraged to report all donors found to have a positive or doubtful reaction as syphilis suspects to the health department. The health department should assist in getting donors with a positive serologic reaction under treatment in the same way in which they are now assisting local draft boards to get a second blood test on registrants found on first examination to have a positive or doubtful reaction for syphilis.

It is felt that if the hospitals of the country will develop a satisfactory system of notification, they will not only contribute to the syphilis control program but

they will render a definite service to a large number of persons who are unaware of the fact that they have syphilis

SUMMARY

1 A questionnaire was sent to 800 hospitals to determine whether or not blood donors found to have a positive or doubtful serologic reaction for syphilis were notified of the results of the test and how they were notified. Replies were received from 603 hospitals.

2 Of the 603 hospitals 65 per cent did not test blood donors for syphilis before their blood was used.

3 Of the hospitals testing donors for syphilis, 12.5 per cent had no method for notification of the donors found to have a positive or doubtful serologic test.

4 In all 16.2 per cent of the hospitals either did not examine donors for syphilis or did not notify them when the serologic test was found to be positive.

5 The person or agency responsible for notifying donors with a positive serologic reaction and the method of notification varies according to the size of the hospital and the type of administrative control.

6 The findings indicate the need in many hospitals for a more definite system whereby prospective blood donors found to have a positive or a doubtful serologic reaction for syphilis may be notified of the result of the test.

ABSTRACT OF DISCUSSION

DR HAVEN EMMERSON, New York: When we are looking around for ways of bringing this problem of syphilis to people's attention, the blood donor system must be recognized as a matter of considerable importance, and here we have an instance of the way it can be used and well used with good results. I hope we can get attention for this by the American Hospital Association and other professional bodies concerned with blood banks and well controlled blood donor systems.

DR JOSEPH W. MOUNTAIN, Washington, D. C.: It is astounding that any hospital should accept donors without a blood test. I am surprised to find that a fair proportion are doing so. That prompts me to ask several questions in respect to this group. You have some six hundred hospitals in the group. I am wondering how representative they are of the hospitals of the United States. Do you think that you got the hospitals which showed the best performance? Would the hospitals whose performance was not so good be the ones who would be likely to fail to send back your questionnaire? Have you any information as to what was done with respect to persons who showed positive reactions? Did the hospitals continue to use them as donors or were they rejected? I noticed that they were not notified of having the infection or 10 per cent of them were not. I noticed too that you classified hospitals as follows and I quote: "municipal, other governmental, private denominational"—and that does not exactly conform to the classification used in the Hospital Register for example of the American Medical Association, which uses the description: "governmental, nonprofit and proprietary." Is the term "private" as herein used intended to be synonymous with "nonprofit," and is "denominational" synonymous with "religious"? If so, what becomes of the other group of voluntary hospitals which do not fall within the categories "private" or "denominational"? Is there any legal responsibility involved in the failure of the hospital to take what would seem to be reasonable precautions against the transfer of infections?

DR EMMERSON: Under the blood betterment it would be impossible to have any blood donor that did not have the blood test before blood was taken.

DR WILLIAM C. WOODWARD, Washington, D. C.: The law, I believe, very generally requires any one who finds that a person who he examines or treats is suffering from syphilis to report that fact to the proper authorities. If such a report states the name of the syphilitic person, surely those authorities get in touch with him, at least unless they are assured that

he is under treatment by some licensed practitioner who has assumed responsibility for the case. If the report describes the syphilitic person only by number—is I believe is sometimes permissible—then he may remain officially anonymous, but only so long as he is known to be under treatment. How is it possible, then, for a blood donor who has been found to have syphilis to remain in ignorance of that fact or to avoid the inconveniences usually associated with it?

DR H. R. O'BRIEN, Hartford, Conn.: Is there not another provision in many states requiring approved laboratories to report to the health department positive Wassermann reactions?

DR EMERSON: If the state system has an approved laboratory.

DR O'BRIEN: In how many states does that arrangement obtain?

DR WILLIAM W. FRYE, Nashville, Tenn.: These problems were brought to our attention several years ago and the present study was undertaken to determine how other hospitals were handling prospective blood donors found to have a positive blood test for syphilis. We too were surprised to find from the survey that there are some hospitals in the United States using blood donors without running a serologic test for syphilis. This question was answered in many instances: "We do not do blood tests on donors used in this hospital." This report is based on a geographically representative sample of hospitals taken from the Transactions of the American Hospital Association for 1940. The type of hospital control such as "denominational," is the classification used by the American Hospital Association. As to the rejection of donors, the donor is often told that his blood is "no good" or his blood is bad or "it won't match." When donors are asked about what they were told they think that all these statements mean that the blood will not match, and they have no idea that the single test indicated that they have syphilis. With regard to legal responsibility, certainly a hospital should be responsible for notifying the person. There are a few states which have laws. New York State for example, requiring that all laboratories report positive blood tests to the health department. With regard to Dr Woodward's question, the reporting of positive bloods to the government agencies does not solve the donor problem. In most cases the prospective donor is seen only once. If his blood test is doubtful or positive on one examination this is not sufficient evidence to make a diagnosis of syphilis, and unless the donor is brought back and checked this is not reported as a case of syphilis. We have found that in many cases in our own hospital the donor had a positive blood and the intern on the case was the only one who knew the result of the test. The donor was never called back and the intern did not report the case as he had only a single blood test, which is not sufficient evidence to make a diagnosis of syphilis. Unless some one in the hospital assumes the responsibility for recheck and notification the donor with the positive test never knows that he may have syphilis. In reporting positive donors to the health department the case is reported from a hospital and it is assumed that the patient is under treatment. With such a method the prospective donor may be reported as a case of syphilis and yet he has never been informed of the fact that he has syphilis. No one has taken the responsibility for getting another blood test or for explaining to the donor the importance of a complete examination and treatment if a definite diagnosis of syphilis is made.

London Fogs—Owens has studied the nature of London fogs and found that the amount of suspended solid particles is proportional to the fog density. He found 1 mg. of solid material per cubic meter of air on a clear day as contrasted with 5 mg. per cubic meter in a dense fog. The latter figure represents 195 tons of suspended solid material over the area of London. He found the diameter of the solid particles to vary between 0.00013 and 0.00026 mm. in diameter. Water to a depth of 0.0014 mm. was condensed on the surface of these solid particles. The number of particles present in such polluted air may rise to more than 50,000 per cubic centimeter. Under these conditions about 500 billion particles per day would be inhaled by an adult person.—West, Edward S. *Physical Chemistry for Students of Biochemistry and Medicine*, New York, Macmillan Company, 1942.

THE HAZARD OF PARALDEHYDE
ADMINISTRATION

CLINICAL AND LABORATORY STUDIES

CHARLES L. BURSTEIN, M.D.
NEW YORK

A number of fatalities following paraldehyde administration have been reported which invariably have been attributed to an idiosyncrasy. However, analysis of reported autopsy findings, observations in the clinic and laboratory investigations on experimental animals lead to the conclusion that pathologic changes following the intravenous administration of paraldehyde are so definite that its use in this manner is not warranted.

Paraldehyde has gained in popularity because of its convenient applicability to produce unconsciousness. It has been administered orally, rectally and intravenously. The doses recommended have been variable. Indeed there are reports of human tolerance of massive doses. As much as 100 cc has been ingested with recovery.¹ For rectal instillation 30 cc has been recommended in the average adult.² Intravenously the injection of fractional doses of 2 to 3 cc until the desired effect is obtained³ has been advocated. Undoubtedly rapidity of absorption is a great factor, since deaths have occurred following the ingestion of 25 cc⁴ and the rectal injection of 12 cc.⁵

Paraldehyde was first used in Italy by Cervello⁶ in 1884 and in England by Strahan.⁷ The first report of a death attributable to this drug appeared in 1890.⁸ Six teaspoons had been given by mouth to an adult delirious typhoid patient. Five minutes later the patient "fell into an unconscious state" and died four hours later from "failure of the heart's action." Since this early publication there have been numerous reports of instances of so-called paraldehyde poisoning or idiosyncrasy to paraldehyde. Only a few of the reports which included autopsy findings will be reviewed briefly.

MacFall⁹ reported the death of a man aged 41 who had ingested about 75 cc of paraldehyde. Autopsy revealed severe congestion of both lungs.

McDougall and Wyllie⁹ reported the death of a psychotic woman aged 44 who drank 4 ounces (120 cc) of paraldehyde. In a few minutes she was in profound coma and showed signs of cardiac failure as evidenced by pallor and rapid, thready pulse. Despite restorative treatment with oxygen she died fifty hours later. At autopsy both lungs were deeply congested and there was considerable mucus in the trachea.

Kotz, Roth and Ryon¹⁰ reported the death of a woman aged 31 who was given 31 cc of paraldehyde rectally for obstetric analgesia. She was a healthy woman and had received no other sedative medication. Ten minutes after administration of the paraldehyde the patient was in deep sleep, the respiratory rate having increased from 20 to 40 a minute and the heart rate from 90 to 120. A half hour later she was in coma with cyanosis, labored and rapid respirations and a rapid, irregular pulse. Three hours later auscultation disclosed a loud blowing murmur over the tricuspid area indicative of failure of the right side of the heart. The blood pressure diminished from 148 systolic and 98 diastolic to 118/58 millimeters of mercury. Despite treatment for heart failure (oxygen withdrawal of 250 cc of blood, digifoline intravenously and 100 cc of 25 per cent dextrose intravenously) pulmonary edema developed and the patient died eight hours after the administration of paraldehyde. Findings at autopsy revealed hypostatic congestion with edema of both lungs and severe dilatation of the right side of the heart.

Fig. 1—Records of dog weighing 10 kg from above downward represent thoracic respiratory movements, abdominal respiratory movements, arterial blood pressure and time at intervals of one second. At 4.5 cc of paraldehyde was injected intravenously in twenty-five seconds. Prior to the injection the control respiratory rate was 14 a minute and the arterial blood pressure (under local anesthesia) was 180 systolic and 100 diastolic. During the course of the injection a period of apnea was observed while the blood pressure fell to 110/40 and soon reached a level at 60/48. In strip B thirteen minutes after the injection the animal was in second plane surgical anesthesia. The respiratory rate had increased to 120 a minute with very shallow excursions. The abdominal respiratory record showed definite accessory abdominal contractions which occurred every eight or nine seconds. The arterial blood pressure was 80/60. In strip C fifty minutes later the animal had regained consciousness and reacted to all forms of stimuli but respirations remained rapid (over 200 a minute) and shallow. Arterial blood pressure still remained at 80/60 (a fall of 55 per cent from the control readings). This animal died eighteen hours later of acute pulmonary edema with dilatation of the right side of the heart.

A case analogous to the one just cited was reported by Shoor.¹¹ Twelve cc of paraldehyde in 6 cc of benzyl alcohol and 30 cc of isotonic solution of sodium chloride was administered rectally to a healthy obstetric patient aged 21. Three and one-half hours later the patient was cyanotic and comatose. Respirations were 48 a minute and labored, the pulse rate was 148 a minute and irregular and the arterial blood pressure had fallen from 130/90 to 96/56. Despite oxygen therapy and cardiac supportive measures pulmonary edema ensued and the patient died twenty-one and one-half hours after the administration of paraldehyde. Autopsy revealed acute pulmonary congestion and edema.

REPORTS OF CASES

Two fatalities are here reported

CASE 1—A man aged 58 was to undergo an endothermic resection of a carcinoma of the cheek and excision of the cervical glands. Several months previously a similar resection had been performed during chloroform anesthesia. The use of intravenous paraldehyde was proposed for the second operation because of the supposedly greater safety of the latter drug. Morphine sulfate $\frac{1}{4}$ grain (0.01 Gm) and scopolamine hydrobromide $\frac{1}{10}$ grain (0.0004 Gm) was administered subcutaneously at 1:30 p.m. At 2:45, just prior to anesthetization, the patient's arterial blood pressure was 140/90, pulse rate 82 a minute and respiratory rate 18 a minute. At 2:57 intravenous injection of paraldehyde was started. Twenty-three cc was injected in nine minutes when the patient appeared to be in second plane anesthesia but operation could not be started because of coughing. Five cc more was injected in thirty seconds. The arterial blood pressure had fallen to 100/80 with a pulse rate of 100 a minute. The patient however was not sufficiently anesthetized and another 5 cc was injected in thirty seconds. This was further complicated by attacks of coughing so that additional injections of 4 cc of paraldehyde in thirty seconds, followed by 3 cc in twenty seconds were administered. This made a total of 35 cc of paraldehyde before the patient appeared ready for operation. At this time the patient's blood pressure was still 100/80, the pulse rate 96 a minute and the respiratory rate 56 a minute. An endotracheal tube was passed by the nasal route to assure a patent airway and operation was begun and completed in thirty-five minutes. At this point the patient seemed to be recovering from his anesthesia, as evidenced by roving eyeballs, swallowing, coughing and responding to supraorbital pressure. The patient was nevertheless returned to the ward with the nasotracheal tube in place. The tube was removed at 5:40 when the patient had regained his reflexes and maintained a patent airway. The pulse rate was then 114 a minute and respirations were 36 a minute. At 7:10 the patient became cyanotic. Oxygen by nasal catheter and an intravenous infusion of 1,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride were started. The patient died at 8:45 despite artificial respiration with oxygen for the last twenty minutes. Permission for a postmortem examination was not obtained.

Fig 2—Records of dog weighing 14 Kg from above downward represent thoracic respiratory movements, abdominal respiratory movement, arterial blood pressure and time at intervals of one second. At 1:7 cc of paraldehyde was injected intravenously. The respiratory rate increased from 16 to 72 a minute while the arterial blood pressure previously recorded under local anesthesia fell abruptly to the zero level. Artificial respiration immediately instituted at 2 was valueless.

CASE 2—An obese white man aged 38 presented signs of acute peritonitis. His condition was complicated by delirium tremens. Celiotomy under ether anesthesia disclosed pan-

creatitis. Eighteen hours after the operation signs of alcoholic encephalopathy developed characterized by irrationality and delirium tremens. Morphine was ineffective as a sedative. Paraldehyde was then ordered, 15 cc to be administered by mouth every six hours. The first two doses had little or no effect in quieting the patient. A third dose was given in the

Fig. 3—Showing pulmonary hemorrhages in the right side of the heart

evening, but restraint was still necessary. Three hours after the third dose of paraldehyde the patient was found dead in bed. At autopsy severe pulmonary congestion was observed.

In the reported fatalities following administration of paraldehyde death occurred by the development of acute failure of the right side of the heart and autopsy showed pulmonary congestion with edema and dilatation of the right side of the heart. That these pathologic complications were not a coincidence was borne out by studies on experimental animals.

EXPERIMENTATION

To evaluate the effects of intravenous paraldehyde on the cardiovascular and respiratory systems, 28 dogs, 36 cats and 24 rabbits were used.

In the dogs, control arterial blood pressure readings were recorded by cannulating a femoral artery under local anesthesia with 2 per cent procaine hydrochloride. Control respiratory movements were obtained by applying pneumographs to register thoracic and abdominal movements. No sedative or other medication was used. Paraldehyde 0.5 cc per kilogram, was then administered intravenously at the rate of 1 cc in five seconds. Under these conditions, 16 of the 24 dogs displayed general anesthesia lasting seventeen to sixty-four minutes (group 1), while the other 8 died within five minutes (group 2).

In group 1 the same sequence of events affecting the cardiovascular and respiratory systems was repeatedly reproduced and is illustrated in figure 1. The arterial blood pressure fell abruptly during the injection of paraldehyde to attain a level averaging a reduction of more than 50 per cent of the control level. This low level was maintained during the anesthetic phase and remained after the animal regained consciousness. The heart rate showed a compensating tachycardia from 80 to more than 200 a minute. Respiratory changes were likewise consistent. Immediately after injection of paraldehyde there was apnea for several seconds. This was followed by rapid, shallow respira-

11 The paraldehyde used was obtained from the Bellevue Hospital Pharmacy from the supply used routinely for clinical patients.

tions, the rate increasing from 14 to 20 to as much as 200 a minute while the minute volume decreased sharply. Accessory muscles of respiration were used often, especially the abdominal muscles. Coughing occurred frequently. Cyanosis, which became progressively more intense, was noted, determinations of the oxygen of the arterial blood showed a reduction from 17.3 to 8.8 volumes per cent. The majority of the animals in this group (11 out of 16) died six to twenty-four hours after anesthesia. Autopsy revealed acute pulmonary edema with multiple areas of gross hemorrhage in both lungs, dilatation of the right side of the heart and congestion with edema of all the viscera.

The remaining 5 animals in this group survived but looked weak and had anorexia. Three of them died within two weeks and autopsy revealed multiple pulmonary hemorrhage.

In the second group of 8 dogs which died within five minutes after paraldehyde injection the respirations rapidly increased in rate while the arterial blood pressure fell precipitously (fig 2). Respiratory and circulatory collapse appeared simultaneously. An attempt at immediate artificial respiration by rhythmic pulmonary inflation of oxygen through a tube passed into the trachea was of no avail. Autopsy revealed massive diffuse pulmonary hemorrhages and dilatation of the right side of the heart distending the pericardial sac. To obtain a better knowledge of what occurred, paraldehyde was injected intravenously in a group of 6 dogs and 6 cats whose chests were opened in the midline so as to expose the heart and lungs. This was done under light anesthesia with soluble pentobarbital and artificial respiration maintained by rhythmic inflation of air through a tracheal tube.

Kodachrome motion pictures were made in two of the experiments. It was observed that immediately following the injection of paraldehyde the lungs suddenly blanched while the right side of the heart, both the ventricle and the auricle dilated. The left ventricle contracted forcefully for a short time while the lungs

To obviate a species susceptibility, similar experiments were repeated on 36 cats and 24 rabbits with identical results. It was further determined that the minimum anesthetic dose (smallest dose that produced anesthesia) when paraldehyde was administered intravenously was 0.3 cc per kilogram of body weight in

Fig 5—Upper record of myocardiogram of dog weighing 12 kg. Middle record arterial blood pressure. Bottom record the time at intervals of one second. Following the injection of 6 cc of paraldehyde intravenously the myocardiogram showed definite cardiac dilatation.

all 3 animal species. The minimum lethal dose (dose at which 50 per cent of the animals died) was found to be 0.45 cc per kilogram in cats and rabbits and 0.50 cc per kilogram in dogs. These figures represent a low margin of safety.

SUMMARY

Paraldehyde administered intravenously is not as safe as is generally believed.

Autopsy findings in reported clinical fatalities are similar to those reproduced in experimental animals, namely dilatation of the right side of the heart with pulmonary hemorrhages and edema.

Clinically, these fatal complications are preceded by signs of acute failure of the right side of the heart.

Experimentally the rapid development of cardiac dilatation and pulmonary hemorrhages can be observed in the open chest following administration of intravenous paraldehyde.

477 First Avenue

ABSTRACT OF DISCUSSION

DR RALPH T. KNIGHT, Minneapolis: Dr Burstein has done a service in collecting these case reports of others, presenting the informative details of the 2 cases which were available to him and following them through with corroborating animal experimental evidence of the mechanism of death by paraldehyde. His finding of the extremely low margin of safety between the minimum anesthetic dose and the minimum lethal dose is especially noteworthy and should be well considered by any one who contemplates using this drug. Probably few members of this section have had occasion to use paraldehyde. It was used by a good many in the latter part of the last century and in very recent years we have been reminded of its availability and serviceability. The uses for which it has been especially advocated are, first the control of alcoholic and psychotic confusion and delirium states and second, the control of anxiety and distress during the first stage of labor. These uses call for an amnesic or hypnotic rather than an anesthetic. Possibly, if the clinical employment of paraldehyde is confined to this mild effect and larger doses with their more potent effects are meticulously avoided, the margin of safety may be much wider. Still one must heed the warning voice¹ by Dr Burstein. Obstetric analgesia and anesthesia are relatively much less satisfactory than our present methods.

Fig 4—Dilatation of the right side of the heart

began to be mottled by areas of hemorrhage which increased steadily in size. After three to five minutes cardiac arrest supervened. Figure 3 shows the pulmonary hemorrhages and figure 4 the cardiac dilatation observed in one experiment. Figure 5 is a graphic representation of the cardiac dilatation obtained by means of a myocardiograph.

results in surgical anesthesia. In their desire to improve their obstetric service many may still be tempted to explore the clinical possibilities of paraldehyde. In public hospitals, especially with limited budgets for more expensive drugs, this may be true. My only use of paraldehyde has been in the Minneapolis General Hospital, where it has been employed only for control of unmanageable alcoholic and psychotic patients on their admission. It has then been administered intravenously in doses of 2 to 8 cc., just sufficient in each case to obtain relative quietness. I believe that no more than 10 cc. has ever been injected at this hospital. We have had no fatalities, but in the last two years other resources have displaced this method. The impressive warning is that the pathologic condition which causes death, as shown by Dr. Burstein, develops not necessarily at once but during a period of time following anesthesia, and there is no criterion while we are administering the drug to tell us whether or not we still have given too little to cause the fatal changes. If one employs it one must do so after weighing the possibilities and deciding that, under the individual circumstances, it is still the most serviceable choice. It is a little difficult to think up illustrative instances in which this would be true. I should like to ask Dr. Burstein whether he believes that the initial toxic effect is on the capillaries and tissues in both the lungs and the heart or whether the pathologic condition in either one is secondary to the failure of free circulation of blood through the other.

DR C. L. BURSTEIN, New York. In answer to the question of Dr. Knight on the toxic effect, whether it is on the capillaries or on the tissue itself, I have done several experiments, as yet unpublished, which lead me to believe that paraldehyde is a capillary poison. I have also done other experiments, such as injecting paraldehyde, not intravenously, but into the left ventricle, and in those experiments no pulmonary hemorrhages were observed but the animals died promptly, probably from some cerebral accident.

THE USE OF PROGESTERONE IN THE TREATMENT OF POST- PARTUM PSYCHOSIS

HARRY J. SCHMIDT, M.D.
CONVENT, LA.

A review of the literature shows that this condition occurs in every 400 to 1,000 deliveries. The variation of the figures is due to the fact that there is no line of demarcation between extreme nervousness with minor changes and a definite psychosis. Statistics show that postpartum psychosis constitutes about 10 per cent of the female admissions to the psychopathic hospitals.

The duration of the condition is from several weeks to eight months, the prognosis for ultimate recovery in the true postpartum psychosis being good.

The cause of this psychosis is as yet a matter of speculation and theory. No common findings are noted among the case reports. Psychogenic factors are not always present. Infection, shock and difficult labors are not constantly found. As a rule there is no evidence of toxemia. The literature is confusing and contradictory, indicating that the real cause is as yet unknown. The definite predisposing factor is delivery.

The nature of the psychosis indicates that the condition is definitely a clinical entity. No record was found of a postpartum psychotic patient ever developing a psychosis subsequently from any of the numerous stresses and strains of a lifetime. The favorable prognosis for ultimate recovery and the common recurrence of the psychosis following subsequent pregnancies indicate that the condition is probably due to some distur-

bance of a physiologic nature resulting from the sudden termination of pregnancy. Complete recovery without specific therapy in a period of weeks or months tends to prove definitely that some readjustment is accomplished with time.

The symptom complex of the psychosis varies with each person, the whole gamut of psychiatric illnesses being observed in these patients. The detailed classification of the psychiatrist is based solely on the behavior of the individual and is purely symptomatic. It has no important bearing on either the cause or the treatment.

REPORT OF CASE

A white woman aged 21 was seen throughout the pregnancy. It was noted that she was unusually quiet and calm, especially for a first pregnancy. The patient was healthy, well adjusted for married life and very desirous of a child. She was advised to go to a hospital for delivery because the pelvic measurements were slightly under normal, although no grave difficulties were expected. She was delivered in a state hospital by low forceps with episiotomy. The labor was normal and of ten hours' duration. There were no complications of the puerperium, and the patient was discharged on the fifth day.

Two days after her return home she developed noticeable nervousness, suffered from insomnia and eventually became hysterical. The condition became progressively worse, and the patient developed a definite psychosis. She was readmitted to the same hospital to a gynecologic service. A pelvic examination showed no abnormal findings, and she was discharged within twelve hours.

The following day she became irrational, had convulsive seizures and was admitted to the neuropsychiatric ward. The case was completely worked up with a diagnosis of postpartum psychosis-schizophrenia.

The physical and neurologic examinations disclosed no abnormalities. The essential laboratory findings showed nothing of importance. The family history revealed that a married sister became somewhat nervous after pregnancy. The mental status of the patient was recorded as follows: "Behavior: general excitement, constant stream of talk. Flight of ideas, mostly about religion. Mood: sadness. Conduct: feeling of guilt, thinks she is going to Heaven. Sensorium: disoriented as to time and place." It was necessary to restrain the patient, she refused to eat, and nourishment was given through a tube. Infusions were also used. In a febrile period the temperature went as high as 103 F., the cause of which could not be determined. During this time the patient had a profuse uterine hemorrhage which was almost fatal. Several transfusions were given. The patient eventually recovered without specific treatment and was discharged as apparently normal after a stay of five weeks in the hospital.

Two weeks after her return home she again developed the psychosis. On the fifth day she began menstruating, and the psychosis cleared up one week after the period. For two weeks she was apparently normal, attending her household duties and going about as usual. At the end of the two weeks the psychosis returned. She again menstruated on the fifth day, and the psychosis terminated one week after the menstrual period. On the third month the psychosis advanced five days and suddenly disappeared with the advent of menstruation. The onset of the psychosis could be noted several days in advance by slight irritability, otherwise the patient was apparently normal during the sane phases.

The cyclic recurrence of the psychosis in the latter half of the menstrual cycle suggested that the condition had some relationship with the hormone balance. This explanation appeared to be most logical and the institution of endocrine therapy was begun at ovulation. Progesterone¹ 1 mg. was given daily for the first three days. At this time the patient showed signs of increasing nervousness and irritability, fore-

¹ The majority of the progesterone used in this case was furnished in the form of progesterone by the C. W. Carrick Company.

casting the probable onset of the psychosis. The dose of progesterone was then increased to 10 mg daily, with immediate effect on the symptoms. The nervousness and irritability disappeared, the patient became more quiet and calm and continued so with the daily injections. In spite of the dread of the hypodermics, the patient readily admitted that the injections had a most "soothing effect." The cumulative action of the hormone was very apparent. There was practically a minor change of personality. The patient became more congenial and developed an intense interest in both household duties and other diversions. Her mental acumen was far superior to that noted in any of the normal phases since the onset of the psychosis. There was no indication of the recurrence of the psychosis. The 10 mg doses of the drug were continued until two days before the expected menstrual period. The period was delayed three days and was normal in all respects. During the injection of progesterone no sedatives or other medications were given.

COMMENT

As this entity was assumed to be of endocrine origin and satisfactory results were obtained with the use of progesterone, the rationale of treatment should be discussed. During pregnancy, progesterone is furnished by the corpus luteum for the first two or three months. At this time the function is taken over by the placenta.² The specific action of the hormone is to protect the pregnancy. This is accomplished by suppressing³ or modifying⁴ uterine contractions due to its nullifying effect on the pituitary oxytocic hormone.⁵ There is definite clinical evidence that the hormone has other less important roles. Improvement has been observed in psychosis of pregnancy by the administration of this hormone. Other clinical disorders were effectively relieved by its use. I have noted that the patients who have uterine contractions during the latter months of pregnancy, indicating a deficiency of the hormone, are always of nervous temperament. There is definite indication from clinical observations and from the actual administration that the hormone has some sedative action either directly or indirectly on the central nervous system. During pregnancy large amounts of the hormone are furnished by the placenta. Duyvene de Wit and Oppers⁶ found that a placenta weighing 480 Gm contained 640 micrograms of progesterone, whereas a mature menstrual corpus luteum contained about 16 micrograms.

Since the predisposing cause of postpartum psychosis is the termination of pregnancy, one may well consider the events that take place at that time. The patient is deprived of the baby and the placenta. The loss of the former definitely relieves the patient of an added burden. It should be quite significant that the sudden removal of the placenta, which has been furnishing the patient with a superabundance of progesterone, would not be unlikely to cause a disturbance of the hormone equilibrium. During pregnancy the patient becomes adjusted to the gradual change of ratio between the hormones, the progesterone becoming physiologically

increased to serve its purpose. At the termination of pregnancy the patient is suddenly and abruptly deprived of a large store of progesterone, thus disrupting the hormone balance.

Frank⁷ in 1931 originally pointed out the imbalance between the estrogenic and corpus luteum hormones. He suggests that "it would thus appear that the continued circulation of an excessive amount of female sex hormone in the blood may in labile persons produce serious symptoms, some cardiovascular, but the most striking, definitely psychic and nervous." Since the corpus luteum hormone is concerned in the metabolism of estrogens, accelerating the excretion of estrogenic hormone,⁸ the sudden loss of the placenta would result in an excess of estrogenic hormone in the circulation.

It must be admitted that a psychosis may result from a hormone imbalance, as minor mental changes have frequently been noted in premenstrual tension. Israel⁹ suggests that "premenstrual tension is caused by the presence of unantagonized estrogen. This implies that the primary cause is deficient ovarian luteinization with decreased production of progesterin." An analogous condition exists following pregnancy, the cause being more apparent than can be explained during the menstrual cycle. This greater disturbance of the hormone balance post partum probably accounts for the more serious mental changes, namely the definite psychosis. A periodic postpartum psychosis may be considered in the same category as an extreme premenstrual tension.

A suitable explanation of why a given patient should develop the psychosis may be found with further study along these lines. It might be interesting to note the significance of the weight of the placenta. The key to the solution may possibly be concerned with the excretory rate of the hormones. Frank⁷ also noted in 1931 that "a comparatively small amount of female sex hormone may produce striking effects in a given person if the renal excretory level is high."

Furthermore, the relationship of the corpus luteum to the adrenal cortex may be of some importance. Progesterone has been isolated from the adrenal cortex in considerable quantities.¹⁰ In reporting a series of psychiatric cases, Hoff and Shaby¹¹ stated that in 4 cases of mental confusion following the puerperium there was good response to the administration of adrenal cortex extract.

The case reported appears to be typical of the condition presenting the usual causes considered by the psychiatrist. Yet the periodic return of the psychosis associated with the menstrual cycle would definitely rule out the commonly supposed causes. The profuse hemorrhage has been noted in a number of the cases reported and occurred in 2 other cases to my personal knowledge. The rather frequent occurrence of the hemorrhage suggests somewhat that the causation is of endocrine origin. The case reports are meager and offer no information of value from the point of view of endocrinology. One report mentioned a cyclic recur-

ience of the psychosis but did not furnish any menstrual data. Kraines,¹² in discussing this condition, states that, "in those patients wherein the menstrual period is associated with emotional disturbances, testosterone propionate has been found useful." The action of this hormone would be the same as that of progesterone as regards their relationship to the estrogenic hormone. Physiologically progesterone would be the indicated hormone for treatment.

In the 2 other cases familiar to me the psychosis persisted for eight months, during which time menstruation did not occur. It is quite likely that the reestablishment of the menstrual cycle in the case reported was responsible for the psychosis becoming periodic. It may be suggested that in the treatment of the continuous psychosis an attempt be made to reestablish the menstrual cycle by the use of the suitable endocrine therapy, large doses of progesterone being given during that particular phase. The rationale for this is quite apparent.

Time may prove the importance of the corpus luteum hormone in this as well as in other conditions. It no doubt plays the principal role in keeping the patient stable and probably accounts for the feeling of well-being experienced by some during pregnancy as compared to a nervous tension in the nonpregnant state. It is the probable cause for the absence of migraine during pregnancy. The use of the hormone is certainly indicated for the control of minor emotional disturbances frequently noted following delivery. The early use of it may prevent the development of a psychosis. Progesterone may be of definite value in the treatment of certain psychopathic conditions not associated with pregnancy.

In a review of the literature I was unable to find any case report in which the corpus luteum hormone was used as specific therapy for postpartum psychosis. Realizing that 1 case does not constitute definite proof, I submit this report with my impressions so that more complete work may be done by the men who care for these unfortunates, so badly treated by nature.

SUMMARY

The constant precipitating factor and the favorable prognosis for recovery indicate that postpartum psychosis is a clinical entity and is due to some disturbance of a physiologic nature resulting from the sudden termination of pregnancy.

The recurrence of the psychosis associated with the menstrual cycle in the case reported suggested that the condition had some relationship with the hormone balance. The most probable disturbance of the balance would likely be due to the sudden loss of a superabundance of progesterone furnished by the placenta. Excellent results were obtained by the administration of this hormone.

The loss of a large amount of progesterone at delivery and its accepted relationship to premenstrual tension indicate that the psychosis probably results from an excess of this estrogenic hormone in the circulation.

It is suggested that adequate dosage of progesterone be used in the treatment and that the menstrual cycle be reestablished if necessary.

Clinical Notes, Suggestions and New Instruments

'CABLE RASH'—A NOTE ON A NEW CLEANSING MIXTURE

GEORGE E. MORRIS, M.D. AND IRVING R. TABLERSHAW, M.D. BOSTON

"Cable rash" or "Haloway dermatitis" has been known to the medical profession for more than twenty-five years. Yet in this period of war as in 1918, cases are being seen of intractable "chloracne" occurring in navy yard workers along both seacoasts despite the use of the most modern protective creams and ointments. This type of dermatitis is seen also in those engaged in the manufacture of the chlorinated naphthalenes and diphenyls, as well as in men in other occupations

Fig. 1—Haloway spots before cleansing

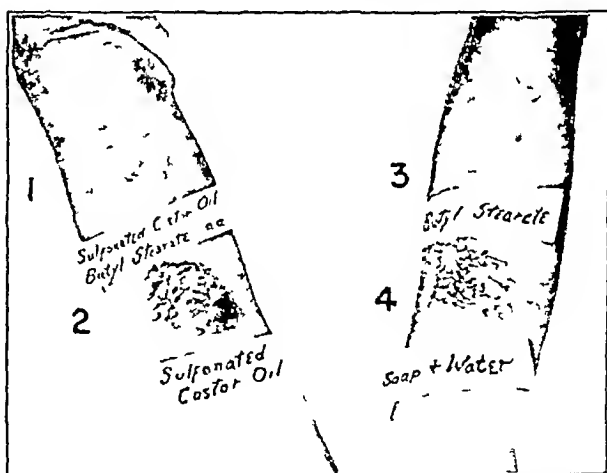

Fig. 2—1 comparative results of cleansing with mixture described. 2 sulfonated castor oil—note Haloway still present on skin. 3 butyl stearate followed by soap and water and 4 soap and water—note Haloway still on the skin.

in which these substances are employed. Such cable rashes are thought to be due at least in part to the blocking of the pores by the synthetic waxlike substances whose tumes solidify when they reach the skin. Acute yellow atrophy of the liver has been described as occurring from these chlorinated substances, but the present brief note is not concerned with this phase of their toxicity.

We feel that the removal of all the solid waxlike particles from the skin at the end of each work period would probably prevent the occurrence of this type of dermatitis with this in mind we have experimented with the removal of these substances from the skin.

A black chlorinated naphthalene (Hilowax) was dissolved in chloroform and rubbed into the skin. Various mixtures of soaps, wetting agents and organic solvents were tried, and from the beginning it was obvious that soap and water would not completely remove the wax from the skin. It was finally found that butyl stearate would remove the wax from the pores, this could then be washed off with soap and water, leaving the skin clean. Since this involved two maneuvers, namely, first rubbing the oil well into the skin and then washing with soap and water, it was deemed more practical to evolve a one maneuver cleansing agent.

Such an agent consists of

	Gm or Cc
White corn meal	50.0
Butyl stearate	22.5
Sulfonated castor oil (75 per cent oil)	22.5
Oleic acid	5.0

Mix the oils together and then add the corn meal

This mixture is to be rubbed onto the skin and then removed with water. The procedure should be repeated. Butyl stearate has been found to be a bland, nonirritating substance, and no cases of dermatitis from its use have been reported. At room temperature it is a clear, colorless odorless, stable oil with a chemical formula $C_{18}H_{35}O_2$. At a temperature below 68 F it is a solid waxlike substance. It is important to use castor oil which contains 75 per cent of sulfonated oil and 25 per cent of inert material, for oils with greater percentages of inert materials have been found less effective. The accompanying illustrations show the efficacy of this method as compared with the use of soap and water alone or of sulfonated castor oil alone. We suggest that this mixture be tried as a cleansing agent both by workers before the acne develops and by those suffering from the disease.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT
AUSTIN E. SMITH, M.D., Secretary

STAPHYLOCOCCUS TOXOID (DIGEST-MODIFIED)-LEDERLE

Staphylococcus Toxoid (Digest-Modified) Lederle was presented by Lederle Laboratories, Pearl River, N. Y., as staphylococcus toxin treated with pepsin until it will no longer hemolyze rabbit erythrocytes or produce necrosis in the skin of a susceptible rabbit, for the prophylaxis or treatment of infections caused by the staphylococcus. The firm submitted labels, package insert and advertising circular and a galley proof of an article entitled "Staphylococcal Toxoid Prepared by Peptic Digestion" by I. A. Parfentjev, Frances L. Clapp and A. Waldschmidt, which, when presented by the firm, was to appear in the *Journal of Immunology*.

The firm claims that the use of peptic digestion of staphylococcus toxin decreases the possibility of allergic reactions and allows increased dosage of staphylococcus toxoid with less local or general reaction. However, the amount of evidence submitted at the time of presentation does not appear to warrant these claims, and further investigation seems advisable.

In view of this, the Council voted to issue a preliminary statement asserting that at the present time there is insufficient evidence to warrant acceptance of Staphylococcus Toxoid (Digest-Modified)-Lederle for inclusion in New and Nonofficial Remedies as it appears to be an unessential modification of a toxoid for which the firm is already licensed, but that further consideration will be given to this particular preparation when additional evidence is available.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

DEXTROSE (See New and Nonofficial Remedies, 1942, p. 418)

The following products have been accepted
PACIFIC COAST STERILE SOLUTIONS CO., LOS ANGELES

Dextrose 5% W/V in Distilled Water 1,000 cc bottles. Each hundred cubic centimeters contains 5 Gm. of dextrose.

Dextrose 10% W/V in Distilled Water 1,000 cc bottles. Each hundred cubic centimeters contains 10 Gm. of dextrose.

Dextrose 5% W/V in Isotonic Sodium Chloride Solution 1,000 cc bottles. Each hundred cubic centimeters contains 5 Gm. of dextrose and 0.9 Gm. of sodium chloride U. S. P.

Dextrose 10% W/V in Isotonic Sodium Chloride Solution 1,000 cc bottles. Each hundred cubic centimeters contains 10 Gm. of dextrose and 0.9 Gm. of sodium chloride U. S. P.

THEOPHYLLINE WITH ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1942, p. 332)

The following additional dosage forms have been accepted
H. E. DUBIN LABORATORIES, INC., NEW YORK

Ampules Solution Aminophyllin 0.48 Gm. in 20 cc

Tablets Aminophyllin 0.2 Gm. (3 grains)

Tablets Aminophyllin 0.2 Gm. (3 grains) (Enteric Coated)

VITAMIN A (See New and Nonofficial Remedies, 1942, p. 539)

The following product has been accepted

WHITE LABORATORIES, INC., NEWARK, N. J.

White's Oleo-Blend Vitamin A Capsules Each capsule contains 25,000 U. S. P. units of vitamin A derived from fish liver oils.

ASCORBIC ACID-U. S. P. (See New and Nonofficial Remedies 1942, p. 564)

The following dosage forms have been accepted

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Tablets Ascorbic Acid 25 mg., 50 mg. and 100 mg.

ISOTONIC SOLUTION OF SODIUM CHLORIDE (See New and Nonofficial Remedies, 1942, p. 425)

The following product has been accepted

PACIFIC COAST STERILE SOLUTIONS CO., LOS ANGELES

Isotonic Solution of Sodium Chloride 1,000 cc bottles. Each hundred cubic centimeters contains 0.9 Gm. of sodium chloride-U. S. P.

NICOTINIC ACID-U. S. P. (See New and Nonofficial Remedies 1942, p. 561)

The following dosage forms have been accepted

WALKER VITAMIN PRODUCTS, INC., MOUNT VERNON, N. Y.

Tablets Nicotinic Acid 20 mg., 50 mg. and 100 mg.

SODIUM ASCORBATE (See THE JOURNAL, July 10, 1942, p. 883)

The following dosage form has been accepted

GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Ampul Solution Sodium Ascorbate 500 mg. in 10 cc

SULFANILAMIDE (See New and Nonofficial Remedies, 1942, p. 142)

The following dosage form has been accepted

HORTON & CONVERSE, LOS ANGELES

Sulfanilamide Tablets 0.324 Gm. (5 grains)

POLIOMYELITIS INHIBITION

The possibility of aborting experimental poliomyelitis in monkeys by the prophylactic or therapeutic injection of a second neurotropic virus has been suggested by Jungeblut and Sanders¹ of the Department of Bacteriology, Columbia University. Two years ago they adapted the New Haven strain of poliomyelitis virus to white mice by intermediary passage through cotton rats². Thus adapted the virus lost most of its original pathogenicity for monkeys. When it was injected intravenously into monkeys the murine virus was electively localized in the central nervous system, where it persisted for relatively long periods of time without producing symptoms. On recovery from this subclinical infection the monkeys had hardly any acquired immunity against subsequent inoculation with virulent strains of poliomyelitis. This nonpathogenic mutant of virus from monkeys has been propagated for two hundred passage generations in mice, during which time it has increased a thousand fold in pathogenicity for mice with further loss of its immunizing potential for monkeys³. The murine virus is readily cultivated in embryonic mouse brain-serum ultrafiltrate⁴. Among their early observations there was suggestive evidence of a strong biologic antagonism between this murine mutant and the virulent parent strain of the virus.

The occurrence of antagonisms between microorganisms is interesting. As far as bacteria are concerned the antagonistic action is usually attributed to specialized enzymes, such as pyocyanase or gramicidin. Virus antagonisms, however, are apparently determined mainly by biologic reactions of tissue cells of the host. Thus the yellow mosaic virus, a mutant of the common

light green mosaic disease of tobacco, will not propagate within (or is not propagated by) tobacco tissue cells already infected with the common mosaic disease⁵.

Magrassi,⁶ Doerr⁷ and others showed that an intracerebral injection of herpes virus following shortly after a corneal or intradermal herpes infection causes a mutual extinction of the effects of both injections. Puntum⁸ noted that a rabbit which receives a series of intravenous injections with fixed rabies virus after a subdural infection with ordinary street virus fails to develop rabies. Hoskins⁹ demonstrated that an intramuscular injection of a neurotropic strain of yellow fever virus protects animals against simultaneous infection with a highly pathogenic viscerotropic strain. Findlay and MacCallum¹⁰ found that monkeys inoculated subcutaneously or intraperitoneally with a mixture of neurotropic and pantropic strains of yellow fever usually survive, while control monkeys inoculated with either virus alone usually succumb. Of even greater interest is the antagonism between either canine distemper or lymphocytic choriomeningitis virus and experimental poliomyelitis¹¹. Interest here arises largely from the fact that there are no known fractional antigens common to these two interfering agents and the virus of poliomyelitis.

In Jungeblut's studies² a similar antagonistic action was noted between his nonpathogenic murine strain and virulent poliomyelitis monkey strains. He found, for example, that an in vitro mixture of murine virus and simian poliomyelitis is often noninfectious on intracerebral injection into monkeys, while the same dose of the simian virus given alone almost invariably caused lethal paralytic symptoms. This antagonism was readily titrated. On testing various virus mixtures, he found that 0.5 cc of a 1:10 dilution of murine virus would counteract at least a hundred minimum paralytic doses of simian poliomyelitis, irrespective of the simian strain used. Biopsy shows that injection of such a balanced mixture is not followed by propagation of either virus. Symptomless survival from such a balanced inoculation is rarely followed by an appreciable acquired immunity to poliomyelitis.

In a later series of experiments, Jungeblut tested the prophylactic effects of this viable murine vaccine. He found that three to five doses of the murine virus given at daily intervals by the intravenous route from one

day to two weeks before the intracerebral inoculation with simian poliomyelitis would greatly reduce the paralytic symptoms. Out of 26 monkeys thus treated only 13 developed recognizable paralysis. All of the 19 control monkeys developed partial or complete paralysis. Even more definite antagonistic effects were demonstrated in animals in which the murine vaccine was given therapeutically. Daily intravenous injections of the murine virus were begun three to five days after intracerebral inoculation with the simian virus and continued for five to seven days. Of the 45 monkeys thus treated, 24 (53 per cent) did not show demonstrable symptoms of poliomyelitis. All the 30 untreated controls developed well defined or complete paralysis.

The essential task before the New York investigators at present is the development of a basic theory to explain the observed murine-simian antagonism. The antagonism cannot be explained on the known facts or accepted theories of specific anaphylaxis or immunity. Most theories thus far proposed have been oriented about the known facts of cytologic "blockade" or of cytologic enzyme exhaustion. In his latest study, however, Jungeblut has demonstrated that murine virus partially inactivated by exposure to ultraviolet radiation retains in large measure its prophylactic and therapeutic effects. This strongly suggests that the antagonistic factor is a noninfectious chemical inhibitor formed or secreted by the murine virus. If this can be definitely established, the new "poliomyelitis inhibin" may well prove to be a basic discovery of major practical interest. The work is being continued by the New York investigators.

Meanwhile two additional instances of viral interference of major research interest have been reported by other investigators. Delbrueck and Luria¹² found that a mixed infection of a bacterium with two different strains of bacteriophage, both of them feeding on (or being multiplied by) the same bacterial host, resulted in a complete suppression of the growth of one bacteriophage. Andrews¹³ reports that cultivation of influenza A virus in a simple tissue culture renders the culture unable to support the growth of a neurotropic variant of the same strain of influenza A virus. The altered tissue culture, however, is still able to support the multiplication of an unrelated virus, such as lymphogranuloma venereum. Andrews believes the most likely explanation of this "interference" is the using up of enzymes or of specific food materials essential for the growth of the influenza virus. This is essentially a renaissance of the initial Pasteur theory of acquired immunity, which was discarded with the discovery of diphtheria antitoxin.

DEATHS OF PHYSICIANS IN 1942

During 1942 a total of 3,328 obituaries of physicians were published in *THE JOURNAL*. Of these, 3,211 were classified as of the United States and 117 as of Canada, 85 were of women. The American Medical Directory Report Service, including the United States, possessions and Canada, recorded 3,580 deaths, including 3,353 for the United States alone, or 142 more than the 3,211 published in *THE JOURNAL*.

A net increase to the profession of 1,952 resulted from the 5,163 graduates of medical schools in the United States for 1942. The increase does not include graduates of foreign schools who were first licensed in this country in 1942. These statistics are not yet available, but 626 were recorded during the calendar year 1941.

Age—The average age at death was 65, as compared with 65.9 in 1941 for 3,354 deaths published in *THE JOURNAL*. Twenty-two physicians died between the ages of 25 and 29, 66 between 30 and 34, 63 between 35 and 39, 83 between 40 and 44, 104 between 45 and 49, 175 between 50 and 54, 278 between 55 and 59, 415 between 60 and 64, 551 between 65 and 69, 548 between 70 and 74, 369 between 75 and 79, 312 between 80 and 84, 178 between 85 and 89, 36 between 90 and 94 and 9 between 95 and 100. The age could not be ascertained on 2 deaths.

Causes—Heart disease again accounted for the greatest number of deaths among physicians. Coronary thrombosis and occlusion caused 627 deaths, and other coronary diseases and angina pectoris 143. Other diseases of the heart and myocardium were responsible for 838 deaths. In this group cerebral hemorrhage also appears with 393 deaths, arteriosclerosis 250, and cardiovascular renal disease and chronic nephritis 217. Cancer and tumors in various forms accounted for 181 deaths, those of the gastrointestinal tract totaling the largest group of 141. In the general classification, 239 deaths were grouped under diseases of the respiratory system, except tuberculosis. Of these lobar pneumonia was recorded for 23 deaths. There were 139 deaths classified under diseases of the gastrointestinal tract, 40 under diseases of the genitourinary tract, 46 under diseases of the nervous system and 29 under diseases of the blood, including pernicious anemia, leukemia and Hodgkin's disease. Diabetes accounted for 72 deaths, tuberculosis, all forms, for 36, bacteremia, septicemia, pyemia and abscess for 30. Senility and ill defined causes were responsible for 40 deaths, and 38 physicians died following an operation. Rheumatism and arthritis caused 8 deaths, influenza and other infectious diseases 5, disease of the bones and osteomyelitis 4, anaphylaxis and allergy 3, diseases of the thyroid 2 and Addison's disease 2. One death each was recorded from alcoholism, posterior mediastinitis, beriberi, virus pneumonia, tetanus, typhus fever, acute

¹² Delbrueck, M. and Luria, S. F. *Arch. Biochem.* 1: 111, 1942.
¹³ Andrews, C. H. *Brit. J. Exper. Path.* 23: 214, 1942.

epidemic hepatitis, psychosis with drug addiction, pellagra, carcinoma following x-ray burns, the result of exposure to x-rays for a number of years, and malaria.

Accidental Deaths—One hundred and twenty-three accidental deaths were recorded. Automobile accidents accounted for 50 deaths. Falls were responsible for 25 and then airplane accidents 10, trains 7, burns 6, drowning 4, bullet wounds 3, and overdose of medicine, poison and asphyxiation 2 each. A street car accident caused 1 death and illuminating gas 1. The type of accident was not specified for 2 deaths. Fractures, which have been classified under falls, were of the skull, hip and femur. There were 6 unexplained fractures. One death occurred when the physician slipped down an icy mountain slope, and 1 was caused by a ruptured intestine when the physician was squeezed between two operating tables.

Suicides and Homicides—Forty-seven suicides were recorded, 18 being attributed to bullet wounds. Next in order of classification of method were poison 8, hanging or strangulation 5, cut artery 3, overdose of drugs 2, falls (jumping) 3 and gas 2. One death occurred from injuries received when the physician threw himself under a train. The method was not reported in 5 suicides. Only 1 homicide was reported, a bullet causing death.

Miscellaneous Positions—Among the decedents were 253 who had been teachers in medical schools, 149 of whom had reached the professorial rank. There were 13 deans. One hundred and twenty had been members of boards of education, 128 health officers, 105 members of boards of health, 59 mayors, 55 coroners, 42 authors, 29 bank presidents, 25 legislators, 18 missionaries, 17 editors, 15 members of city councils, 15 pharmacists, 7 police physicians or surgeons, 6 clergymen, 5 fire surgeons, and 3 each had been judges, lawyers, postmasters and sheriffs. Two were justices of the peace. Three were interns. One was chairman of the revision committee of the Homeopathic Pharmacopoeia, 1 was a member of the U. S. Pharmacopoeia and 1 had been Secretary of the Interior, Postmaster General of the United States and chairman of the Republican National Committee.

Of the total of 3,211 physicians, 533 had served in World War I, 58 in the Spanish American War and 3 in the Civil War. Thirty-five were members of the U. S. Public Health Service, 20 of the U. S. Army, 15 of the Veterans Administration, 14 of the U. S. Navy and 9 of the Indian Service. One served in the Philippines during the insurrection. Three were members of the National Guard. Six had been members of the medical reserve corps of the U. S. Army and 1 of the reserve of the U. S. Public Health Service, 33 had been medical examiners of draft boards for World War I and 22 for World War II. The classification "Selective Service System" was reported in 17 deaths.

Association Officers—Among those who died, 2 had been President of the American Medical Association, 3 Vice President, 1 Trustee, 1 member of a Council, 1 secretary of a Council, 1 Vice Speaker, 2 members of the Committee on Medical Preparedness, 17 section officers and 32 members of the House of Delegates. There were 39 presidents of state medical societies, including 1 president of the Alaska Territorial Medical Association. One was president of the Medical Association of the Isthmian Canal Zone. There were 6 secretaries of state societies and 213 presidents of county medical societies.

Military Service—Eleven physicians died in action during World War II and 37 while in military service. Of those killed in action, 4 died in the Philippine Islands, 1 at Corregidor, 1 when a ship in the Caribbean was torpedoed, 1 somewhere in the Pacific, 1 at Java, 1 at sea (unknown) and 2 at Guadalcanal. Of those who died while in military service, 9 were killed in airplane accidents and 3 were reported suicides. Coronary diseases were responsible for 7 deaths, acute epidemic hepatitis 1, septicemia 1, carcinoma of the sigmoid 1 and uremia 1. Two died when the barracks were destroyed by fire and 1 was killed by the accidental discharge of a sentry's gun. 1 in a shipwreck off the coast of Newfoundland, 2 in automobile accidents and 1 in a train accident. The rest were classified under various physical conditions.

The general total of 3,211 includes deaths that occurred in Turkey, Iran, Scotland, Ecuador, China, Mexico, France, Sweden, Spain, Alaska, Hawaii and Puerto Rico.

Current Comment

SYRUP SUBSTITUTES

Restrictions on the use of sugar have resulted in renewed interest in syrup substitutes. One recent communication¹ presents a brief review of previous discoveries and recommendations in this field. Agents which have been used in the past as sugar substitutes include honey, glycerin, xercharin and molasses. After listing a series of agents used to prepare experimentally artificial syrups containing a water soluble gum and soluble saccharin, the author concluded that syrups of satisfactory stability could be prepared with sodium alginate, Irish moss, tragacanth and locust bean gum as thickening agents and saccharin as a sweetening agent. However, because of the uncertainty of the supply of tragacanth and locust bean gum, domestic sodium alginate and Irish moss may receive more attention. The thickening agents experimented with by the author include citrus pectin, methyl cellulose, Irish moss, acacia, locust bean gum, alginate, apple pectin, karaya gum, glycerin and sorbitol. It is evident that much more work is needed in this field and that the ideal and universal sugar substitute remains to be perfected.

VIRUS (?) PNEUMONIA

An atypical form of pneumonia has recently appeared widely in various areas of the United States. Baker has reported a series of observations which may throw new light on some of the problems engendered by this disease. In a communication to *Science* he¹ reports the isolation of a virus involved in a respiratory tract infection in cats, observed in the past year in the north-eastern part of the United States. The main characteristics of the disease in cats are its highly infectious nature, debilitating effects and long course. Its respiratory nature is recognized by sneezing and coughing, which is accompanied by a mucopurulent discharge from the eyes and the nose. The existence of pneumonia is not ordinarily determined by the usual clinical examination, but necropsy reveals grayish densely consolidated areas in the anterior lobe of the lungs. The virus was obtained by inoculating intranasally into mice suspensions of lungs from cats with typical clinical symptoms. The agent was easily transferred to eggs, which had been incubated for five days, by inoculation into the yolk sac. Attempts to pass the agent through Berkefeld filters gave irregular results. The nature of the agent, however, became apparent when sections of the yolk sac membrane stained by a suitable means revealed numerous elementary bodies similar to those of psittacosis. Centrifugation of the infected mouse lungs and yolk sac suspensions removed much of the infective agent from the supernatants and concentrated it in the sediments. This is added evidence that the observed elementary bodies are the etiologic agents. A number of instances of contact between sick cats and people who subsequently developed atypical pneumonia have appeared. Complement fixation tests have been made, but the results in both cats and man have so far been somewhat inconclusive. The conclusion is, however, that this respiratory disease in cats is due to a virus that forms elementary bodies and that this virus is the same as or crossrelated to the one causing at least some of the cases of so-called atypical or virus pneumonia in man. In another preliminary communication from Eaton and his colleagues² an infectious agent from cases of virus pneumonia was transmitted to cotton rats. Of 131 cotton rats receiving material from cases of virus pneumonia, 35 developed lung lesions. By serial intranasal passage of lung suspensions from animals which developed lesions on the first passage, strains of an infectious agent from 6 cases of virus pneumonia were adapted to cotton rats. After four to six passages the adapted strain produced gross evidence of lung involvement in over 90 per cent of the animals inoculated but seldom caused death. The lung lesions were patchy red-gray in appearance. Microscopic examination of sections of lungs showed an infiltration of the septums with polymorphonuclear leukocytes and mononuclear cells and hyperplasia of the alveolar epithelium. By cross inoculation and neutralization tests, antigenic relationships between six

established strains were demonstrated. Cotton rats immunized by two successive intranasal inoculations with adapted strains were solidly immune to reinoculation with a specimen of infectious human lung which produced definite lesions in control animals. The appearance of nonbacterial lung lesions in cotton rats after inoculation of material from cases of virus pneumonia suggests that a virus-like agent was transmitted and established by serial passage. Strains adapted to cotton rats were related to the agent in human material by cross immunity tests. This agent, which is presumably a filtrable virus, differs from the psittacosis-like virus and from other known viruses which can infect cotton rats by the intranasal route. Eaton and his co-workers conclude that to present the evidence for the causal relation of this agent to the most common form of "atypical pneumonia" must be considered incomplete because of irregularities in the neutralization tests, particularly those with human serum.

MEDICOLEGAL CASES 1936-1940

The House of Delegates in 1932 adopted a resolution suggesting the publication in book form of the medicolegal abstracts that are weekly printed in *THE JOURNAL*. An initial volume was published that year containing the abstracts that had previously appeared in *THE JOURNAL* during the calendar years 1926-1930. In 1936 a second volume, also covering a five year period, was published. Now a third volume is available which includes abstracts published from 1936 to 1940 inclusive. These books are bound in durable library buckram, are adequately indexed to enable the user readily to find a discussion by the courts of the particular medicolegal problem that prompts his search and contain complete tables of cases giving complete titles to all the cases abstracted. The current volume includes over eight hundred abstracts. The cases abstracted deal with a wide variety of subjects of interest to physicians and others concerned with matters of medicolegal import. A seventy-four page index begins with reference to cases involving abandonment of patients in relation to malpractice and concludes with a reference to a court discussion on zoning regulations as they apply to mental and nervous disease hospitals. Between these two index subjects are to be found references to practically all the important reported decisions of courts during the five year period in which joint issues of medicine and law have been involved. As reference sources these volumes are unique in their field and they should be in every library, legal as well as medical. The preface to the second volume called attention to an oft repeated truism that a man who acts as his own attorney has a fool for a client and to the fact that the idea prompting the publication of these abstracts in *THE JOURNAL* and in book form has not been to qualify physicians to assume the role of counsel for themselves or for others. Rather the idea has been to exemplify the medicolegal problems that have been before the courts so that physicians may more intelligently meet such problems when they arise in their own personal experiences and perhaps to aid physicians in avoiding some of the pitfalls into which their fellow physicians have fallen.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

DIABETES AND MILITARY SERVICE

ELLIOTT P JOSLIN, M D

Boston

Liberal estimated there are about 800,000 living persons with diabetes in the United States, and one might suppose that among them would be many who could serve their country as members of the armed forces. However, when one looks at the problem more closely and studies it from a statistical point of view, the number of those who could serve usefully dwindles to so few that it would not make their selection worth while. Furthermore, after induction, the impossibility of always assuring a proper diet, the possibility of increase in severity even among those not taking insulin when inducted, the recurring necessity for creation of medical boards to decide on their physical status when transferred from station to station or when hospitalized for any trivial ailment, combined with the responsibility of the government for their care during the rest of their lives, uphold the present rule to forego their

Department, Metropolitan Life Insurance Company. Assuming 5 per cent available there would be only 2,500 to 1,800 men.

A third method is open for appraising the number of those who are diabetic who could be considered army material. This is to make a study of a series of diabetic persons. For this purpose the first 10,000 cases coming for diabetes to our clinic were examined. Of this number approximately 15 per cent had benign glycosuria and not true diabetes as diagnosed when first seen, only those cases diagnosed as diabetic were included in this study. Among this group of 8,500 there were 780 males between the ages of 18 and 39. Of this 780 there were only 139 who could be considered eligible for the draft, 641 would have been ineligible because of either physical defects or severity of diabetes.

The average age of the 139 available at their first visit was 31.1 years. Already they had had diabetes 22 years when first seen. By 1942, ten years after the last of the 139 had come to the office, the surviving patients of the original 139 numbered 126, 13 having died (9.4 per cent). The causes of death were coronary disease 7, pneumonia 3, tuberculosis 1, coma with infection 1, and 1 death with the diagnosis of diabetes with hypertension and nephrosis.

Insulin was not taken when the patients were first seen, with the exception of 1, who had a dose of 5 units of insulin on one day during a five day stay at the hospital. Data for subsequent use of insulin and data regarding dietary habits are shown in the accompanying table. According to the table, which included both living and those who had died, 105 patients are still taking no insulin as reported by various follow-up letters, later check-ups or return visits. Four were taking insulin irregularly and 25 regularly, varying over a period from one to ten years from the time of first observation, thus evidently having contracted diabetes at least of moderate severity.

Ninety-four of the original 139 patients were on unrestricted diets, eating everything, but "light on pastries and sweets." Eleven were on moderately restricted diets.

As reported in the 1942 follow-up letters, 102 patients were well and considered themselves in good health. Most of them were working at the time, although many had had a complication of some sort since their first visit. These complications, arising from the time since they were first seen, as reported by the patients or their doctors, included carbuncles 2, abscesses and infections of the skin 7, duodenal ulcer 5, disease of the gallbladder 4, arteriosclerotic impurities including cardiac changes 9, arthritis 3, bursitis 2, thyroid disease 2, colitis 2, fractures 1, varicose veins 1, sinus infection 1, genitourinary 1. These complications were

Diet and Insulin at Least Ten Years After Their First Visit of 139 Diabetics Selected as Possible Candidates for the Armed Forces

Use of Insulin	Unrestricted Diets	Restricted Diets	Total
No insulin	94	11	105
Insulin irregularly	1	3	4
Insulin regularly (5 unknown)	3	22	25
Total	98	36	134

services. Especially does this seem wise when considered in connection with the need for workers in civilian life.

Statistically one can assume that two thirds of the 800,000 persons in the country who have diabetes are above the age of 40 years and of the remaining one third only two fifths are males. From the 107,000 males with diabetes under 40 years of age one must again deduct about 17,000 under 18 years of age, thus leaving by such an estimate around 90,000 total diabetic males between the ages of 18 and 40 years. In all probability not more than 10 per cent and far more likely 5 per cent would meet army requirements, and when one allows for disbarment because of dependents and other nonphysical reasons the final number available for induction would surely not exceed 4,500 and more likely 2,250 individuals.

If one bases statistical reasoning on the number of diabetic persons, assumed as 800,000 for the whole country and allocated according to the age distribution of the National Health Survey as applied to the population of 1940, the total for ages 18 to 44 is only a little over 50,000 and between 18 and 39 years about 36,000. These allocations were made for me by the Statistical

the only ones reported or that came under observation. There would be, obviously, many more not reported in a period from forty years ago, when the first patient was seen.

Among those later taking insulin, 4 were subject to reactions, including 1 with severe reactions. One patient had coma twice, and another's diabetes became very difficult to control.

If the 139 cases culled from the entire 10,000 glycosuric or 8,500 diabetic are utilized for computing the total number of the 800,000 in the country diabetically available, we have 13,062 individuals. Since these are 31.1 years old when first observed by us, the number with dependents and in essential occupations would be unusually large quite apart from physical considera-

tions, and it should be safe to reduce these figures by two thirds to approximately 4,000 men.

It thus appears both by arbitrary statistical estimates as well as by computations, based on an actual study and selection from a series of 8,500 persons diagnosed as having diabetes, that in the United States today the number of diabetic persons available for the Army or Navy lies between 4,500 and 1,800 men. With these figures in mind, the diabetic quota useful for military service is relatively so insignificant, the hazards which both the diabetic and the government would undergo if they were inducted are so great and the need for their services in civilian occupations, where they would be less exposed to complications, so apparent, that the present rule to omit them from the draft appears proper.

ARMY

NEW BRIGADIER GENERALS

Col Albert W. Kenner of the U. S. Army Medical Corps has been promoted to brigadier general for his highly efficient work in North Africa. This is the officer to whom Brig. Gen. Larry McAfee, the assistant surgeon general, referred in his opening remarks in the first broadcast, December 26, sponsored by the American Medical Association in the present radio program entitled "Doctors at War." Among other things, General McAfee said "I cite with keen pleasure the fact that one of the senior surgeons of the North African task force was promoted to brigadier general in recognition of his highly efficient operation of the medical field service in the face of greatest difficulties." General Kenner was born in Massachusetts in 1889, was awarded a Ph.D. in 1910 and an M.D. in 1915 at George Washington University, and graduated from the Army Medical School in 1917, in which year he was commissioned in the medical corps. He has been awarded the Distinguished Service Cross, the Silver Star and the Purple Heart.

Col Fred W. Rankin, M.C. President of the American Medical Association, senior consultant in surgery, and Col Hugh Jackson Morgan, M.C., senior consultant in internal medicine in the office of the Surgeon General, Washington, D. C., have been created temporary brigadier generals.

AUTHORIZE CORPS OF PHYSICAL THERAPY AIDES AND OF DIETITIANS

The President has signed the bill (H. R. 7633) which authorizes the creation of a corps of physical therapy aides and a corps of dietitians in the Army of the United States. According to the *Army and Navy Journal* the members of these corps will come largely from physical therapists and dietitians now on duty with the medical department on a civil service status. The desire to send these women overseas and to protect their rights as belligerents is responsible, it is said, for the plan to give them military status. In general, military pay, including allowances, will be the same or slightly more than civil service pay. The act authorizes a director of each of these corps with relative rank of major, with other members holding relative rank of captain, first lieutenant and second lieutenant. Pay of members of the corps would be the same as pay of regular army officers without dependents of the fourth, third, second and first pay periods.

PAY OF ARMY AND NAVY NURSES INCREASED

The President has signed a bill (H. R. 7633) which increases the pay of army and navy nurses. As far as the act relates to nurses, it accomplishes two objectives: (1) it gives nurses pay of their relative rank and (2) it provides increased relative rank for some nurses. In explanation the *Army and Navy Journal* says that nurses and head nurses have relative rank of second

lieutenant and will receive the pay of the first pay period (\$1,800), together with allowances. Chief nurses have relative rank of first lieutenant and will receive the pay of the second pay period (\$2,000) together with allowances. The new bill gives relative rank of colonel and pay for the sixth pay period (\$4,000) to the superintendent of the army nurse corps. All ranks, in addition to base pay, will receive longevity at 5 per cent for each three years of service up to thirty years. A clause in the act protects some nurses who would have lost pay under the new act.

LARGE CLASS OF MEDICAL ADMINIS- TRATIVE OFFICERS

A large class graduated on December 19 from the Medical Administrative Officer Candidate School operated at Camp Berkeley, Texas, by the Medical Replacement Training Center. This class was four times the size of the class graduated in September. The ceremonies were attended by distinguished guests including Major Gen. Henry Terrell Jr., commanding general of the 90th Motorized Division stationed there, Col. Henry A. Finch, Camp Berkeley commander, Hon. Will W. Hair, mayor of Abilene, Malcolm Meek, president of the Citizens National Bank of Abilene, Dean Walter H. Adams of Abilene Christian College, Dean W. B. McDaniel of McMurry College and Dr. William T. Walton, vice president of Hardin-Simmons University.

The address by the Surgeon General of the Army, Major Gen. James C. Magee, was read by Col. Frank Wakeman, and the diplomas and commissions were presented by Brig. Gen. Roy C. Hefebower, commandant of the Medical Replacement Training Center. In this largest officer candidate school class were thirteen Negroes receiving commissions as second lieutenants, the largest colored contingent to date. After the ceremonies the new officers were given ten day graduation leaves prior to reporting to their first stations for assignment to duty.

THREE HOTELS AT MIAMI BEACH TAKEN OVER BY ARMY

Three of the largest hotels at Miami Beach, the Ponceast, the Tower and the Gulf Stream apartments were taken over by the War Department on December 17 for conversion into hospitals for the Army Air Forces. The hotels were obtained by leases. Of the three the Ponceast is the oldest, built in 1923, the Tower was built in 1935 and the Gulf Stream apartments in 1925.

ARMY PERSONAL

Dr. William C. Menninger, Topeka, Kansas, has been commissioned lieutenant colonel in the U. S. Army Medical Corps and assigned to duty as consultant in psychiatry.

NAVY

THE NAVY NEEDS YOUR BINOCULARS

The U S Navy sometime ago made an urgent appeal to all persons in the United States who own binoculars to offer them to the Navy, and only six thousand persons in the entire country have done so.

In the first world war more than fifty thousand binoculars were offered, and of those which were accepted all but one were returned to their owners at the end of the war. Optical firms in this country are doing their best to meet the demands of our military forces, but the making of binoculars requires special materials, time and skill. The problem is further complicated by the great demands of the air forces, which require special optical instruments such as the stereoscopic height finder and the elbow telescope."

NAVY PERSONALS

The name of Capt Edward C White, U S Navy Medical Corps, was sent to the Senate with recommendation for promotion to rear admiral. Captain White was head of the Inspection Division of the Bureau of Medicine and Surgery in Washington. Lieut (j g) Beulah Ann Buchanan, U S Navy Nurses Corps, chief nurse of the U S Naval Hospital at Great Lakes, Ill., is being relieved from duty there to report for service outside the continental United States. Her position will be taken over by Lieut Mary Martha Heck, U S N N C, who has been transferred from Quantico, Va.

Dr George M Caldwell, formerly resident physician at the Greenbrier Hotel, White Sulphur Springs, W Va., has been commissioned a lieutenant in the U S Navy and is stationed at Norfolk, Va.

CIVILIAN DEFENSE

NURSING EXECUTIVES FOR EMERGENCY
BASE HOSPITALS

The Office of Civilian Defense, Washington, D C., has issued Circular Medical Series No 24 which states that the Surgeon General of the United States Public Health Service has authorized the appointment of a limited number of qualified nurses with supervisory and administrative experience who could be sent to emergency base hospitals when activated to serve as nursing executives. They will be offered appointments in the Public Health Service on an inactive status and will be called to active duty by the Surgeon General on the recommendation of the state chiefs of Emergency Medical Service and regional medical officers only if their services are required at emergency base hospitals because of a military necessity. When on duty they will be entitled to payment by the Public Health Service according to their experience and qualifications at per diem rates based on annual salaries of \$2,600 or \$2,300 and necessary travel and maintenance when away from their usual places of residence.

The number of such nurses to be recruited in each state should be equivalent to twice the number of affiliated units actually being formed in that state. Qualified nurses should be nominated by coastal state chiefs of Emergency Medical Service in

consultation with the state nurse deputy and the directors of affiliated units in his state.

For appointment in the United States Public Health Service, candidates must have not less than two years' experience in hospital ward or operating room supervision in a hospital approved by the American College of Surgeons and the American Medical Association. They must be under 55 years of age and in good physical condition. Although their appointments obligate them to serve in an emergency base hospital in their regions if called to duty by the Surgeon General in a wartime emergency, they may resign their appointments in the Public Health Service at any time to accept assignments in the Army or Navy.

State chiefs of Emergency Medical Service may obtain the necessary application forms for these appointments from the regional medical officers. These forms should be filled out and sent to the appropriate state chief of Emergency Medical Service who will transmit them with his approval, to the regional medical officer, who will forward the applications with his endorsement to the Emergency Medical Section, United States Public Health Service, 2000 Massachusetts Avenue, Washington, D C.

MISCELLANEOUS

AMERICAN OPTICAL COMPANY
AWARDED ARMY-NAVY E

Ceremonies were conducted at the headquarters of the American Optical Company, Southbridge, Mass., Nov 30, 1942 for the award of the Army-Navy E. This award comes from combined Army and Navy boards of recognition for the quantity and quality of output, the avoidance of work stoppages, the overcoming of production obstacles, the training of additional labor forces, capable management, utilization of subcontracting facilities and satisfactory records on health accidents, working conditions and plant protection. The award consists of a flag to be flown above the establishment and of a lapel pin to be worn by each employee of the company symbolic of their contribution to victory in this war. The award was presented to the American Optical Company by Brig Gen Burton O Lewis and was accepted by George B Wells, president of the company. This company has been producing optical goods for one hundred and nine years and many of its products today are aiding in the war effort. The company, in cooperation with the Surgeon General's Office, has designed a mobile optical unit to handle spectacle repairs in the field and several of these units have already been built. The company supplies goggles for aviators, ski troops, navy lookouts and gunners and for mechanized troops, as well as for industrial workers on the home front. The company has made a wide variety of diagnostic and examining instruments for examining recruits and aiding in guarding the vision of service men.

BOOKS FOR RUSSIAN MEDICAL STUDENTS

Students in the First Kharkov Medical Institute formerly at Kharkov, Russia, have written letters of appreciation to the Russian War Relief, Inc., for American medical textbooks, which have been sent by the hundreds to the Soviet Union to help prepare more doctors for work with the Russian army. When the Germans occupied Kharkov, the Kharkov Institute, one of the largest medical schools in the world, was moved to Chiklov, where classes were in full swing within a week after the student body and faculty left Kharkov. Russian War Relief, Inc., is sending still more of all kinds of up to date medical textbooks for Soviet medical students. Contributions for this purpose may be sent to Russian War Relief, Inc., 11 East 35th Street, New York City.

INFECTIOUS DISEASES IN GERMANY

The *Reichsgesundheitsblatt* (Berlin) of July 29 contains the figures for the infectious diseases in Germany during the first half of 1942.

	1942	1941
Diphtheria	121 602	82 238
Scarlet fever	220 076	125 524
Tuberculosis (lung and throat)	68 500	63 998
Tuberculosis (other organs)	9 693	8 390
Infantile paralysis	609	420
Typhus	2 918	2 552

There were 1,205 cases of bacterial food poisoning as against 947 cases in the first half of 1941.

ALABAMA

Changes in Health Officers—Dr Caroline H Callison, Chatham, will serve as health officer of Washington and Clarke counties.—Dr Elisha Moore, Livingston, health officer of Sumter County, has also been placed in charge of the Greene County department of health.—Dr Julius E Dunn, Florence is the new health officer of Etowah and Calhoun counties, with headquarters in Anniston

DELAWARE

State Medical Election—Dr Lawrence J Jones Wilmington, was elected president of the Medical Society of Delaware at its recent annual meeting to serve for one year beginning January 1, and Dr William O LaMotte, Wilmington, was named secretary. The next annual meeting is planned for Wilmington on October 12 and 13

ILLINOIS

Special Advisory Committee on Industrial Hygiene—Governor Green has appointed the first special advisory committee to the division of industrial hygiene of the Illinois Department of Public Health. Members of the committee are Drs Roland R Cross Springfield state director of public health, and Milton H Kronenberg Chicago, chief of the division of industrial hygiene ex-officio members, Philip H Kreuscher and Joseph H Chivers, Chicago chairmen and vice chairman, respectively, Dr Raymond B Allen executive dean, Chicago Colleges of the University of Illinois William H Donovan, Harry Guilbert A G Hewitt and Oliver E Mount Chicago Dr Nordahl O Gunderson Rockford, Charles G Lanphier Springfield Edward F Schweich, East St Louis and Dr Harold A Vonachen, Peoria. The new committee will aid in the development of state programs of adult hygiene including the control of hazardous working conditions and the care of pregnant women in war industries

Chicago

Personal—Evelyn B Tilden Ph.D. of the Rockefeller Institute for Medical Research New York has been appointed associate professor of bacteriology at Northwestern University Medical School.—Dr William H Lipman, medical director of Swift & Company retired, January 2, having reached his sixty-fifth birthday. Dr Lipman graduated at the University of Illinois College of Medicine in 1904 and joined Swift & Company in the same year

Joint Meeting on Cancer—A joint meeting of the North Side Branch of the Chicago Medical Society and the Institute of Medicine of Chicago will be addressed on January 20 at the Chicago Woman's Club by Drs Paul E Steiner on "Significance of Recent Research on the Causation and Nature of Cancer and the Role of the Clinician in Further Advance," Charles B Huggins "Function of the Prostate and Its Relation to Tumors," and Vernon C David, "Carcinoma of the Large Bowel"

Alien Physicians Eligible for City Positions—Corporation Counsel Barnett Hodes in an opinion December 17 said that alien interns and resident physicians may be hired on a temporary basis for work in the Municipal Contagious Disease Hospital, newspapers reported. Dr Herman N Bundesen president of the board of health requested Hodes opinion after he said his advisory board reported that it would be necessary to close the hospital January 1 if a supply of alien physicians could not be obtained it was stated

INDIANA

Personal—Dr Robert W Reid Union City has been appointed health officer of Randolph County to succeed Dr Andrew M Brenner Winchester who has entered the Navy.—Dr Joseph L Allen, Greenfield has been named coroner of Hancock County

Society Publishes Service Bulletin—The St Joseph County Medical Society, South Bend, brought out its new Service Bulletin in November. The first issue contains twelve mimeographed pages designed primarily to let the men in service know what is going on at home

Society News—Dr Byrl R Kirklin, Rochester, Minn., addressed the Indianapolis Medical Society, November 24 on "Bleeding Lesions of the Gastrointestinal Tract," and the Indiana Roentgen Society on "The Military Situation as It Pertains to Radiologists"—The Spencer County Medical Society, at a meeting in Rockport December 15, decided to forego all regular meetings for the duration of the war because of the small number of members remaining. Meetings will be called to transact special business only.—Dr Maximilian Kern, Chicago, discussed "Endocrinological Types of Obesity" before the La Porte County Medical Society in La Porte, December 17

KANSAS

Society News—The Sedgwick County Medical Society was addressed in Wichita, November 3, by Drs Hugh G Jeter and Harry Wilkins both of Oklahoma City, on "Paracentetic Fluid as an Aid in Diagnosis" and "Injuries to the Covering of the Brain" respectively

Coroners Appointed—Governor Payne H Ratner recently made the following appointments to the position of coroner: Drs Wardie W Weltmer, Beloit, of Mitchell County to succeed Dr Richmond E Bennett and Dr Claud F Young Fort Scott, of Bourbon County to succeed Dr Laurence L Cooper. Dr Bennett and Dr Cooper are in military service

KENTUCKY

Jane Todd Crawford Day—On Dec 13 1942 the first Jane Todd Crawford Day was observed. The day was set apart by an official proclamation of the governor as a part of the sesquicentennial year program commemorating Kentucky's one hundred and fiftieth year of statehood. To mark the event the woman's auxiliary section of the state medical journal was recently dedicated to a review of the first ovariectomy performed by Dr Ephraim McDowell. The cover of the special edition carries a picture "Dawn of Abdominal Surgery," executed by Dean Cornwell for John Wyeth and Brother, Inc Philadelphia. The inside cover contains a reproduction of Beumont and St Martin" another of the series sponsored by Wyeth and Brother. An article on Jane Todd Crawford by George Madden Martin Louisville narrates the complete story of the first ovariectomy performed by Dr McDowell in a pioneer cabin in Danville on Dec 25 1809

MASSACHUSETTS

Public Lectures—A course of free public lectures on medical subjects opened in the Peter Bent Brigham Hospital Auditorium Boston January 3 under the auspices of the Harvard Medical School. Dr George W Thorn Boston, gave the first lecture on "The Role of the Endocrine Glands in Adaptation," and Dr Joseph W Ferrabee Boston the second January 10, on "Newer Knowledge of Vitamins." Other speakers in the series are:

Dr Frank H Ishley Boston January 17 The Supply of Doctors
Dr Frederick J Stare St Louis January 24 How Best to Eat Under War Conditions
Dr Maxwell Pauland Boston January 31 Common Colds and Their Complications
Lieut Col Alexander Marble M C U S Army February 7 The Care of Soldiers in an Army Hospital
Constantin P Yaglou M M I Boston February 14 Problems of Ventilation in the Home
Dr Arlie V Bock Cambridge February 21 Civilian Physical Fitness as a War Measure
Dr Allan M Buller Boston February 28 Healthy Children
Rene J Dubos Ph D, New York March 7 Anti-epileptic and Chemotherapeutic Agents

Library Fund Named for Dr Wilmsky—On Dec 20 1942 special ceremonies were held at the Beth Israel Hospital, Boston, to celebrate the sixtieth birthday of Dr Charles F Wilmsky, executive director and superintendent of the hospital and formerly deputy commissioner of health of Boston. Dr Wilmsky was presented by Judge Abraham E Pimmsk Boston with a bound volume of congratulatory letters from all parts of the country. Judge A K Cohen turned over a sum of money to be known as the Charles F Wilmsky Library Fund, and Mrs Pimmsk spoke for the hospital auxiliary in presenting a fund for the hospital in his name. A portrait of Dr Wilmsky, painted by Jacob Binder, was unveiled by Dr Samuel A Robins Boston. Mr James A Hamilton New Haven, Conn. president of the American Hospital Association also spoke. The *New England Journal of Medicine* commented editorially on Dr Wilmsky's birthday in special tribute. Dr Wilmsky graduated at the Baltimore University School of Medicine in 1904. He was associated for many years with the Boston Health Department. In 1927, as deputy commissioner of health, he was granted a leave of absence to assist in a survey on the health of Palestine. For many years he

was in charge of the health units that were established in the city through the George Robert White Fund. In 1935 Dr Wilmsky was also in charge of a relief project for resident physicians of Boston. He became superintendent of the new Beth Israel Hospital in 1928. He is president of the Massachusetts Hospital Association.

MICHIGAN

Special Lectures—Dr Edward R. A. Merewether, London, England, gave a special informal lecture before the Wayne County Medical Society in Detroit, December 21, on "The Latest Medical Facts from Abroad." A joint meeting of the society and the Detroit Pediatric Society was addressed, December 14, by Dr John Harry Ebbs, associate in pediatrics, University of Toronto Faculty of Medicine, Canada, on "Nutrition in Everyday Practice."

Report on Child Guidance Program—Three child guidance clinics have been established in Michigan in recent months as part of the program of the Michigan State Hospital Commission. Dr Frank F. Tallman, Lansing, who was appointed director of mental hygiene of the commission last year, is in charge of the organization, supervision and coordination of the child guidance clinic system. The clinics are in Muskegon, Saginaw and Kalamazoo and requests have been made to the legislature for three similar clinics to be established July 1. The new clinics are a joint undertaking of the state and the community. The state pays all professional salaries for psychiatrists, psychiatric social workers and psychologists. The community provides office facilities, secretarial services, supplies and equipment. Each clinic has a local advisory committee which acts as a liaison body between the local clinic and the state hospital commission. Its chief responsibility is to raise an annual budget. Complete direction and control of the units rests with the state hospital commission. A similar clinic was opened in Lansing in 1938 and was made possible by a grant to the hospital commission from the Children's Fund of Michigan and contributions from the community. Each clinic will serve a territory within a radius of 60 miles. Consultative diagnostic and therapeutic services are rendered by the clinic.

MINNESOTA

Special Society Election—Dr Paul G. Boman, Duluth, was named president of the Minnesota Society of Internal Medicine at its annual meeting in Duluth recently. Dr Bayard T. Horton, Rochester, vice president, and Dr Reuben A. Johnson, Minneapolis, secretary-treasurer.

Personal—Dr John deJ. Pemberton was reelected president of the Mayo Clinic staff at its recent annual dinner and Dr Frank J. Heck was renamed secretary, both are in Rochester. Dr Russell R. Heim, Minneapolis, has been chosen coroner of Hennepin County. Ralph W. Macy, Ph.D., professor of zoology at the College of St. Thomas, St. Paul, has been named professor of biology at Reed College, Portland, Ore.

MISSOURI

Collection on Ophthalmology—The St. Louis Medical Society announces the gift of Dr Joseph W. Charles, St. Louis, of a collection on ophthalmology. The group greatly augments the library's file on this specialty.

University News—Dr Karl F. Meyer, San Francisco professor of bacteriology and director of the Hooper Foundation, University of California Medical School, delivered the Alpha Omega Alpha lecture, December 9, at Washington University School of Medicine, St. Louis, on "Plague."

Dr Cook Heads Medical Department of Lambert Company—Charles A. Cook, Ph.D., since 1931 research chemist at the Experimental Research Laboratories of Burroughs Wellcome and Company, Tuckahoe, N. Y., is now in charge of the department of medical and biologic chemistry at the Research Laboratories of the Lambert Pharmacal Company in St. Louis. Dr Cook's work has been concerned with vitamins, chemistry of gastroenteric disease, amino acids and pituitary hormones.

Memorial Plaque Honors Dr Coughlin—Friends of the late Dr William T. Coughlin presented a plaque to the St. Louis Medical Society, December 1, to serve as a memorial. The gift was made on the presentation of the first Robert James Terry Lecture, which was established under the will of Dr Coughlin (THE JOURNAL, Nov. 28, 1942, p. 1049). The plaque was presented by Dr Llewellyn Sale. Dr Frederick E. Woodruff introduced the guest speaker, Dr Stuart Mudd, Philadelphia, who gave the first Terry lecture on "Morphology of Pathogenic Bacteria and Viruses as Shown by the Electron Microscope with Some Practical Implications."

NEW JERSEY

Medical Scholarship Established—Princeton University has received a legacy of \$25,000 for the endowment of a scholarship to be awarded annually to "a man of outstanding scholarship, character and promise from the state of New Jersey who intends to make the practice of medicine his life profession."

NEW YORK

Personal—Dr Simon A. King has been named health officer of North Dansville to succeed Dr Alden J. Townsend, who resigned to enter military service. A public celebration was held in Memorial Hall, Mineville, December 1, in honor of Dr Thomas J. Cummins, who has completed twenty-five years of service in Moriah. An illuminated parchment scroll, a desk set and a \$1,000 war bond were presented to Dr Cummins. Dr Herbert M. Lyon, Buffalo, has been elected president of the board of trustees of Taylor University, Upland, Ind.; he graduated at the university in 1925.

New York City

Annual Contin Lecture—Dr Alfred Angrist, pathologist at Queens General Hospital, will deliver the annual Contin Lecture, January 22, on "The Mechanism of Brain Injury in Head Trauma." The lecture is sponsored by the Contin Society of the New York Medical College and Flower and Fifth Avenue Hospitals.

The Harvey Lecture—Dr Fuller Albright, assistant professor of medicine, Harvard Medical School, Boston, will deliver the fourth Harvey Society Lecture of the current series at the New York Academy of Medicine, January 21. His subject will be "Studies on the Pathological Physiology of Cushing's Syndrome."

Hospital Closed to Conserve Oil—The Neponsit Beach Hospital for Children, Rockaway Beach, will be closed to "help the city make up its 10 per cent reduction in fuel oil allowance," newspapers reported January 4. Patients and hospital personnel were to be moved to other city institutions beginning January 5, it was stated. The hospital will be reopened when warm weather returns.

Personal—Dr Nathaniel Smith, former deputy medical superintendent of the Morrisania City Hospital, has been appointed medical superintendent of the Fordham Hospital. Dr Donald D. Van Slyke recently was elected an honorary member of the British Physiological Society. Mr Newman M. Biller, assistant director of the Montefiore Hospital for Chronic Diseases, has been appointed executive director of the Home for Aged and Infirm Hebrews. He will be succeeded at Montefiore Hospital on January 1 by Dr Sigmond L. Friedman.

Lectures on Child Psychotherapy—The Association for the Advancement of Psychotherapy announces a series of lectures on various aspects of child psychotherapy. The first session opened January 13 on "Juvenile Delinquency and Psychotherapy." On January 27 the subject will be "Children's Reaction to the War and Its Psychotherapy." Subsequent topics will be February 10, "Adolescents in Need of Psychotherapy"; February 24, "Mental Hygiene in School and Psychotherapy"; March 10, "The Nutritional Basis of Mental Disorders in Children"; March 24, "Clinical Psychotherapy of the Child"; April 14, "Preschool Education and Psychotherapy"; April 28, "The Role of the Family in the Psychotherapy of the Child," and May 5, "Adult Psychotherapy and Child Psychotherapy." Speakers participating in the entire series are laymen and physicians interested in psychotherapy of the child.

Four Schools Offered for Social Hygiene—The board of education has granted permission to the city department of health to use four schools to give preinduction training courses on Saturday mornings. The board of education had refused to include such a course in the regular curriculum (THE JOURNAL, Dec. 26, 1942, p. 1407). In a letter to the Health Commissioner Ernest L. Stebbins, John E. Wade, deputy superintendent of schools, wrote that should the health officials decide to organize these classes, "the board of education will not identify itself in any way with your proposals and we will not be in any position to advertise the lectures to the students. We will make available premises to you as we would to any other organization but you must undertake the enterprise as a project of the department of health wholly unrelated in any way to the Board of Education." The request for high school instruction in social hygiene was made by Dr Stebbins because of a 20 per cent increase in venereal infection among boys and girls 15 to 19 years old. In granting permission to use the schools, the board stated that any legitimate organization had the right to use the schools on Saturday mornings provided the facilities were available.

OHIO

Changes in Health Officers—Dr Gregory J Nordenbrock, St Marys has been appointed health commissioner for Shelby County, effective December 15, he succeeds Dr Harry Wain, Sidney, who resigned to accept a similar position in Miami County.—Dr Clifford J Baldrige, health commissioner of the city of Hamilton and Butler County for twenty years, has resigned, effective January 1

Medicine in the War—A series of public health lectures opened at the Cleveland Health Museum January 10 with a talk by Dr Neil T McDermott, Cleveland on "War Nerves". The series is sponsored by the Academy of Medicine of Cleveland and other speakers in the group all of Western Reserve University School of Medicine, Cleveland, are

Dr David K Sptler January 17 Controlling Epidemics
Dr Roscoe D Lenz January 24 The Whys of Blood Banking
Dr Robert F Parker January 31 Combating Soldier's Health Hazards
Dr Harold D Green February 7 Body Behavior in Flying
Lnos B Buchanan Ch E February 14 Dispelling Modern Food Fallacies

Citizens' Committee Named for Medical Plan—A citizens' committee has been organized to act as sponsors for the Cleveland Medical Service Association prepayment plan, newspapers report. The Academy of Medicine of Cleveland recently issued a statement indicating that the plan is not a part of the academy's activities. The citizens committee includes one hundred and twenty-seven "leaders in the community's public and professional life. Subscribers to the plan will be limited to single persons with an annual income of not more than \$1,800 and heads of families of not more than \$2,400. The Cleveland Hospital Service Association has agreed to handle sale of service contracts to the public, it was announced.

Health Information Hour Suspended—A new service to the community, which was sponsored by the Cleveland Health Museum in the form of a "Health Information Hour" under the title "Tell Me Doctor" has been suspended during January and February. The service constituted the selection of a group of questions sent in by the public and answered by a board of experts composed of Drs James A Doull, Richard A Bolt, John J Thomas and Helen A Hunscher, PhD all of Cleveland. The questions covered all questions of general interest in the field of human biology, medical science, personal health and community hygiene. The ten best questions received a dollar war stamp. If the experts could not answer the question the inquirer received a book entitled "1680 Health Questions Answered" by Dr William W Bruer, Chicago director, Bureau of Health Education, American Medical Association, and, in addition, three dollars in war stamps. The public was invited to attend the program. It is hoped to resume the feature in March.

Dr Herrick Given Honorary Membership in Denison Foundation—Charles Judson Herrick, ScD, emeritus professor of neurology, University of Chicago School of Medicine, Chicago, and now in retirement at Grand Rapids, Mich., was given the first honorary membership in the Denison University Research Foundation, Granville, in recognition of his years of service to Denison University as professor of zoology and for his achievements as a scientist in the field of neurology. Dr Herrick also gave the first two lectures under the foundation to the Denison student body and the Denison Scientific Association. The Denison University Research Foundation was established by an anonymous donor in June 1942 "to promote, in close cooperation with Denison University or other institutions engaged in like activity, constructive research in the arts and sciences and in any and all fields normally associated with the activities of American colleges and universities, to provide inspiration and leadership to such selected persons as indicate a high type of scholastic endeavor, and who reflect special aptitudes in integrated projects that will contribute to human betterment."

TENNESSEE

Course in Internal Medicine—Dr Robert P McCombs, Philadelphia, recently opened a ten week course in internal medicine for physicians in Chattanooga and Hamilton County under the auspices of the county medical society.

State Supreme Court Upholds Medical School Expulsions—The power of the University of Tennessee College of Medicine, Memphis to dismiss students found guilty by school authorities of stealing examination questions has been upheld by the Tennessee Supreme Court, newspapers reported December 13. Two of five students dismissed by the college in 1940 filed a petition in Chancery Court in Memphis charging that they were dismissed without a proper hearing and seeking reinstatement to the medical school.

TEXAS

Radiological Society Cancels Meeting—The annual meeting of the Texas Radiological Society, which was to be held this month has been canceled. Dr Hermann Klapproth, Sherman, is the secretary.

Physician's Portrait Presented to Medical School—A portrait of the late Dr Meyer Bodansky, who had been associated with the University of Texas Medical Branch, Galveston from 1919 until his death in 1941, was presented to the school by the alumni association during the semicentennial graduation exercises, Dec 18, 1942. Dr Bodansky was born in Elizabetgrad, Russia in 1896. He received his doctor of philosophy degree from Cornell University, Ithaca, N Y in 1923 and his doctor of medicine degree at the University of Chicago in 1935. Dr Bodansky had been, since 1930 serving as professor of pathological chemistry. In 1932 he was visiting professor at the American University of Beirut, Syria. At the time of his death he was also director of the laboratories of the John Seale Hospital.

GENERAL

Exchange Fellowship and Travel Grants Awards Suspended—The U S Department of State announces that for the duration of the war the award of official scholarships fellowships and travel or maintenance grants to students from the United States will be suspended. They will be resumed as soon as feasible. However, the award of fellowships and travel and maintenance grants to citizens of the other American republics for study in the United States will not be suspended or discontinued.

New Motion Picture on the Registered Nurse—The American College of Surgeons sponsored the premiere of a new sound motion picture "R N—Serving All Mankind". A grant from the Becton Dickinson Foundation for the Extension of Scientific Knowledge in cooperation with numerous organizations made the picture possible. The film is suitable for showing by hospitals, nursing associations and all types of civic service and educational organizations. It tells the story of two girls who choose nursing as a career.

Delivers Presidential Address Over the Radio—Irving Langmuir, ScD, delivered his address as retiring president of the American Association for the Advancement of Science over the Columbia Broadcasting System December 26 on "Science Common Sense and Decency". The association postponed its meeting for the first time since the Civil War. Arthur H Compton, ScD, president of the association introduced Dr Langmuir speaking from Chicago. Dr Langmuir spoke from Albany, N Y. Watson Davis, director of Science Service, opened the program from Washington, D C.

Special Society Election—Dr William T Wootton, Hot Springs, National Park, Ark, was named president elect of the Southern Medical Association at its recent meeting in Richmond, Va, and Dr Harvey F Garrison Jackson, Miss, was installed as president. Dr William B Blanton, Richmond, Va, was chosen vice president. The association's award for outstanding original work by one of its members went to Dr Purm H Long, professor of preventive medicine, Johns Hopkins University School of Medicine, Baltimore, for his studies on the sulfonamides. The award was received for him by his associate, Eleanor A Bliss, ScD.

Priorities for "Life and Death" Emergencies in Airplane Travel—Announcement has been made of a class number 5 priority to be granted when necessary for a "life saving" flight under a cooperative program of all airlines. A physician en route to attend an emergency case will be granted the recently established priority as will a child en route to a hospital for an emergency operation of some unusual or critical nature. Persons en route to funerals and other instances sometimes described as "death cases" will not be granted priority. The Regional Air Priorities Offices, which will extend this priority, may be reached through any local airline office.

Pharmaceutical Companies Merge—The Winthrop Chemical Company has absorbed the Albra Pharmaceutical Company, both of New York, and has taken over Albra's assets, properties, trademark and good will. According to an announcement, although Albra ceases to exist its research and manufacturing facilities in Rensselaer, N Y, have been consolidated with those of the Winthrop Chemical Company and its marketing policies remain undisturbed. Dr J Mark Herbert, medical director of Albra, will become assistant to Dr Theodore G Klumpp, president of the Winthrop group, and other Albra personnel will be absorbed. As a result of the

merger, Fairchild Brothers and Foster, a wholly owned subsidiary of Albia has become a wholly owned subsidiary of Wintthrop. The Albia Company was incorporated in New York on Aug 30 1935

Federation of Experimental Societies Cancels Meeting—The executive committee of the Federation of American Societies of Experimental Biology has voted to omit the meeting which was scheduled to be held in Cleveland April 6-10. This action applies only to the federation as such and does not cover any meetings which may be organized by the constituent societies including the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics, the American Society for Experimental Pathology, the American Institute of Nutrition and the American Society of Immunologists. According to *Science* provision will be made for publication in the *Federation Proceedings* of abstracts of such papers as would have been offered for presentation if a federation meeting had been held or which may be offered for presentation at meetings of the constituent societies.

Grants for Research in Endocrinology—It is announced that requests to the National Research Council Committee for Research in Endocrinology for aid during the fiscal period from July 1 1943 to June 30, 1944 will be received until February 28. Application blanks may be obtained by addressing the Division of Medical Sciences National Research Council, 2101 Constitution Avenue Washington D C. In addition to a statement of the problem and research plan or program the committee desires information regarding the proposed method of attack, the institutional support of the investigation and the uses to be made of the sum requested. No part of any grant may be used by the recipient institution for administrative expenses. Applications for aid of endocrine research on problems of sex in the narrower sense cannot be given favorable consideration but the committee will consider support of studies on the effects of sex hormones on nonsexual function, for example, on metabolism.

CANADA

Personal—Dr William E Gallie professor of surgery and dean of the University of Toronto Faculty of Medicine Toronto, has been elected to honorary fellowship in the Royal Society of Medicine.—Dr Ada I Wallace, medical health officer for Emerson and the rural municipalities of Franklin and Montcalm was recently appointed first woman coroner in the history of Manitoba, it is reported.

University News—The two separate health service departments for men and women in the University of Toronto Ontario, have been combined this year to form the University Health Service with Lieut Col Richard W I Urquhart Toronto, as director. Dr Gwendolyn E Mulock Toronto is assistant director in charge of the woman's division. The health service now provides annual physical examinations for all undergraduate students.

PUERTO RICO

Bureau of Health Education—The health education office created in 1940 as an annex to the office of the commissioner of health, Department of Health of Puerto Rico, San Juan has been converted into a bureau and its name changed to Bureau of Health Education and Research in accordance with a recent act of the Puerto Rican legislature. The *Puerto Rico Health Bulletin* states that although the last word of the new title implies scientific investigations the alterations in functions have not yet been defined either by law or administratively and there has been no provision whatever made to justify the change in name. The general objectives are to disseminate health information to teach the underprivileged class in particular and the public at large how to take advantage of the services provided by the various agencies of the insular health department and to help in drafting technical instructions for the use of medical officers nurses social workers sanitarians and other employees of the health department. Its main activities include the editing and publishing of the *Health Bulletin* the general supervision of the library of the department of health and the general preparation and distribution of health material.

LATIN AMERICA

New South American Journals—The *Revista Peruana de Pediatría* the official organ of the Sociedad Peruana de Pediatría, made its first appearance with the June issue. The first issue contained original articles and reports of various general sessions of the Peruvian Society of Pediatrics and a section of medical news. Drs Carlos J Krundieck and Julio

Muñoz Pugliese are the editor and assistant editor respectively. The headquarters of the new journal which will be published every three months are Washington 914 Lima Peru.—The *Avalos Neuro-Psiquiátricos del Fracaso de Mujeres de Bogotá* Colombia has recently appeared. Drs Edmundo Tejada Rico and Luis Jaime Sanchez are the editor and assistant editor respectively.

Death in Other Countries

Sir Norman Walker, formerly president of the Royal College of Physicians, Edinburgh and of the General Medical Council, died Nov 7, 1942 in Midlothian aged 81. Sir Norman graduated at the University of Edinburgh in 1884. After being appointed resident physician in 1885 at the Royal Infirmary Edinburgh he was assistant physician for diseases of the skin and later full physician in the skin department at the infirmary. He was a representative of Scotland for thirty five years on the General Medical Council. He received the knighthood in 1928 following a study of medical education in the United States and India.

CORRECTION

Treatment of Phosphorus Burns—In the abstract of Godding and Nottens article on the treatment of phosphorus burns in the current medical literature department of THE JOURNAL July 25 1942 page 1059 in the last line in the first column the words sodium carbonate should have been sodium bicarbonate.

Government Services

Government Manual for Professional Men

The fall-winter 1942 edition of the United States Government Manual is now available from the U S Information Center or the Superintendent of Documents Washington D C for one dollar, either in money order or check. The Division of Public Inquiries prepares and publishes the manual for the Office of War Information. The book contains seven hundred pages detailing the legislative powers functions, location names and titles of chief officials of all the government departments and agencies. It also contains organization charts a list of current federal publications and an invaluable section on abolished and transferred agencies and functions. It is fully indexed both by subject and by personnel and serves as a ready reference handbook.

Examination for Hospital Training in Dietetics

The Civil Service Commission has just announced a student dietitian examination to fill positions in the Army Medical Center Washington, D C. Sixteen female students will be enrolled in this position on or about September 1 and an additional sixteen six months later. The War Department offers a six month training course in hospital dietetics at the Army Medical Center to those desiring to become graduate dietitians. The students will receive subsistence and quarters and a small remuneration during the six month training period. At the end of the training students are eligible to assignment to positions as apprentice dietitian for a six month period at a salary of \$1440 a year. Those who successfully complete this apprenticeship will be eligible for retention in the service in the position of staff dietitian at \$1800 a year. To qualify for the examination for student dietitian positions applicants must have completed a full four year college course which included appropriate study in chemistry biology social sciences education nutrition and dietetics and institutional management. Applications will be accepted from senior students who expect to complete the required course by Feb 1 1944. Provisional appointment may be made prior to completion of the course but before entrance on duty proof of the completion of the course must be submitted directly to the War Department. There are no age limits for this examination. Applications must be in the office of the commission in Washington by January 9. The examination announcement giving full details may be consulted or obtained at first and second class postoffices (except in the cities where the civil service regional headquarters offices are located where the forms must be obtained from the regional office) or from the commission's Washington D C office. Applications are not desired from persons engaged in war work unless higher skills could be utilized in the new position. War Manpower Commission's restrictions on federal appointment of persons in critical occupations in specified areas are given in form 3289 posted in first and second class postoffices.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec 11, 1942

The Names of Drugs

The war has cut off the large supply of drugs normally imported from Germany, of which many are now manufactured in England. The question of names has arisen. The General Medical Council has published, on the recommendation of the British Pharmacopoeia Commission, lists of approved names of the drugs produced by British manufacturers. The object is to recognize nonproprietary names which can be used freely by manufacturers and avoid the difficulties to physicians and pharmacists which arise from a number of names for the same drug. When any of the drugs for which names have been approved are admitted to the British Pharmacopoeia, the approved name becomes the official title, but recognition of an approved name does not imply that the drug will be admitted. The Pharmacopoeia Commission has formed an advisory committee on nomenclature to assist in the selection of approved names. Suggestions for suitable names are invited from manufacturers interested in the production of drugs for which they are required. The commission hopes that the approved names will be generally adopted and the use of other names avoided.

The commission has laid down the following guiding principles: 1. Names should preferably be free from any anatomic, physiologic, pathologic or therapeutic suggestion. This applies only to chemicals. Such suggestion cannot always be excluded in naming biologic products. 2. The accurate chemical name should be used if suitable. When it is unsuitable an attempt should be made to form a name by combining significant syllables from the chemical name and to include an indication of the potent element or constituent of a compound. Names should preferably not be of more than four syllables. 3. They should be distinctive in sound and spelling and not liable to be confused with others. 4. Names difficult to pronounce or remember should be avoided. 5. Addition of a terminal capital letter or number should be avoided. 6. Names in the current United States Pharmacopoeia should be used either as principal titles or as synonyms. 7. Names in the British Pharmaceutical Codex or in New and Unofficial Remedies should receive preferential consideration. 8. The following terminations should be used as far as possible: -ine for alkaloids and organic bases, -in for glucosides and neutral principles, -ol for alcohols and the phenol group, -al for aldehydes, -one for ketones and other substances containing the CO group, and -ane or -ene for local anesthetics.

Among the approved names already published are Amethocaine hydrochloride, Cyclobarbitone, Diethoestrol, Diodone, Diphenan, Dithranol, Ethisterone, Hexazole, Menthylthione, Meprochol, Mesulphen and Sulphacetamide.

Increase in Tuberculosis Produced by the War

The health of this nation has actually improved since the outbreak of war, but there are certain exceptions. The increase in tuberculosis observed in the last great war has been repeated. In his Malcolm Morris memorial lecture Sir Arthur MacNalty, former chief medical officer of the Ministry of Health, said that tuberculosis was an inevitable result of war conditions, which brought overcrowding, limitation of protective foods, shortage of hospital beds, increased hours of work and general war strain. The great efforts made during the years 1918-1938, which had lowered the mortality from tuberculosis, would be retarded by this second great war. Civilian deaths from tuberculosis in England and Wales had risen from 26,250 in 1939 to 28,669 in 1941.

Counter measures must be applied after the war, and for this purpose more specialists in tuberculosis, more nursing and domestic staff, and more beds will be required. The machinery of organization should be made ready now. Every tuberculous man and woman leaving the fighting services or war industry should be rehabilitated, that is, put in a position to earn a livelihood. He advocated a scheme on the lines of the Papworth Village Settlement as embodying the secret of the successful treatment of tuberculosis. One of the results of the evacuation policy due to the air raids had been to transfer considerable numbers of children from London and other cities, where most of the milk was sterilized by heat to small urban or country districts, where practically all the milk was supplied raw. That was bound to cause a rise in nonpulmonary tuberculosis in children and already signs of this were apparent. He urged people to boil their milk if they could not obtain it pasteurized.

Danger of Nurses Contracting Tuberculosis in Sanatoriums

In the House of Commons the minister of health was asked whether in view of the suggestion that girls should be compelled to take up sanatorium nursing and of the efforts now being made to increase the number of nurses in such sanatoriums he would investigate cases in which nurses had contracted tuberculosis in the discharge of their duties and were now maintained either by public funds or on a sum which did not permit adequate and proper care. He was also asked what steps were taken in his department to ensure the rehabilitation of nurses who contracted tuberculosis when nursing tuberculous patients. He said whether he was satisfied that sufficient financial provision was made for such a nurse to ensure adequate food and clothing and a room apart from the rest of the inmates of the house where she might be more or less segregated.

The minister, Mr. Ernest Brown, said in reply that he would call attention to the statement in a recent report of the Medical Research Council that expert opinion in this and other countries was that the risk of contracting tuberculosis from nursing tuberculous patients in sanatoriums is no greater than that involved in general hospital nursing. A nurse in a tuberculosis institution who contracts the disease is given every care and attention appropriate to her condition by the institution. Arrangements for the care and after care, directed to restore working capacity, are an essential part of the tuberculosis service and apply to nurses as much as to any other person who suffers from tuberculosis.

Early Diagnosis of Pulmonary Tuberculosis by Mass Radiography

Sir Penderell Varrier-Jones, the pioneer of village settlements and therapeutic occupation for the tuberculous, died in 1941. Under the presidency of Sir Harold Whittingham, director general of medical services of the Air Force, the first memorial lecture to Varrier-Jones was delivered by Wing Commander Trull. He said that except in a disappointingly small percentage of cases we were a long way from the diagnosis of early pulmonary tuberculosis. The disease now claimed half the total deaths from all causes between the ages of 15 and 24 years. The best possible tuberculosis service, with every modern equipment had made no improvement toward earlier diagnosis in ten years and the extent of the disease at diagnosis was such that the majority of patients were unsuitable for modern treatment and few survived five years following discharge from a sanatorium. This state of affairs was due to the fact that it was only on the arrival of symptoms, and not always then that the patient sought advice. In x-ray examination we have a method which can reverse all this. The physician can seek out the patient and not wait until the patient seeks him.

The lecturer then gave the results of mass radiography of 40,119 personnel in the Air Force, including the Women's

Auxiliary Service The miniature film could weed the abnormal from the normal but for ultimate diagnosis a large film and full clinical and pathologic examination were necessary. Notwithstanding the fact that these 40,119 persons had been examined and passed by national service boards some six to twelve months previously and that all the men had a stricter examination within the previous six months with a view to selection for special duties, the X-ray examination showed that 65 of these unusually "fit" subjects (22 per thousand) of the 30,130 men exhibited signs of active tuberculosis and 108 (36 per thousand) signs of inactive disease. For the 9,989 women the figures were worse. 38 (38 per thousand) had active and 56 (56 per thousand) inactive disease.

The figures showed that, among our supposedly healthy adolescent and young population between the ages of 18 and 24, 3 per thousand have unsuspected active tuberculosis and that more than 1 per thousand is a potential source of infection, because, unknown to himself, he has a positive sputum. The population at these ages is some 5 million from which it follows that we have among us some 15,000 persons suffering from unsuspected tuberculosis.

Before any extension of mass radiography can take place, much preparatory work must be done because workers associated X-ray examination with disease and economic disaster. Legislation must protect them against loss of employment and reduced standards of life for themselves and their families.

Dermatology in the British Expeditionary Force in France

At the annual meeting of the British Association of Dermatology and Syphilology Dr J. T. Ingram, who was consultant dermatologist to the British Expeditionary Force in France, described his experiences. He was disappointed to find that dermatology in the army is a cloak of respectability for venereology, as syphilis does not account for more than 5 or 6 per cent of venereal disease in the army, and a dermatologist should not be asked to treat gonorrhea, which belongs to the urogenital surgeon. Though there were many branches of special medical and surgical practice—ophthalmology, otology, dentistry, pathology—there was no organization for dermatology or, for that matter, for venereal diseases. He blamed dermatologists to some extent for this. It is seventy years since Hutchinson showed what a considerable part dermatology should play in the medical curriculum and yet its leaders are still content to allow it to remain a trifling decoration on the cloth of medicine instead of insisting on its being an essential fabric.

After conferences at general headquarters it was decided to deal with simple acute dermatoses (impetigo and scabies essentially), acute gonorrhea and the continuation treatment of syphilis in field ambulances. The diagnosis and preliminary treatment of syphilis and venereal sores were conducted at certain casualty clearing stations, where mobile pathologic laboratories and specialist personnel were established. The more difficult chronic and abnormal cases were sent to separate dermatologic and venereal units established at general hospitals at the base. The medical officers for the field ambulances were recruited by calling for volunteers. From these a number were chosen and given a week of intensive instruction at the base where they handled a wealth of clinical material and conducted under supervision, the investigations and technique required of them in the field ambulances. The result was that excellent work was done in them and much wastage of man power in the army was avoided. At the base it was arranged that certain general hospitals should house units for the treatment of dermatologic cases under skin specialists and that others should house venereal units under specialists in venereal disease. Patients who needed hospitalization for longer than twenty-eight days under conditions of static warfare and seven days under active warfare were evacuated to England.

Opposition to the New Regulations for the Compulsory Treatment of Venereal Diseases

The introduction of the compulsory treatment of venereal diseases, as a result of the war, was reported in a previous letter to *THE JOURNAL*. As was to be expected, the new regulation at once aroused opposition. Dr Edith Summerskill, a medical member of Parliament with other women members, has tabled a prayer for its annulment. They think that it will operate unfairly against women and will be ineffective. The minister of health received a deputation from the Association for Moral and Social Hygiene and representatives of women's organizations to discuss the new regulation.

A pamphlet entitled *Venereal Disease Still a Problem in the United States* has been sent to the editors of the medical journals anonymously. It begins by referring to the compulsion existing in many states that prospective mothers and applicants for marriage certificates must have serologic tests. It then says "Nevertheless, judging from an article by de Kruif published in the *Reader's Digest*, September 1942, page 10, the wiping out of venereal disease is just as much a problem as ever." Quotations on the dangers of antisyphilitic drugs from the *Lancet* follow.

New Photographic Method for Identifying Human Remains

The trial of a man aged 49 at the Central Criminal Court for the murder of his wife occurred recently. The skeleton of a woman was found under a paving stone of the cellar of a Baptist chapel adjoining premises where he worked as a fire watcher. The chapel was damaged in an air raid and the body was found by a demolition worker. A fire occurred in the cellar four days after the woman disappeared, on April 11, 1941. There were signs of burning on the left side of the remains. The question of identity offered difficulty. Dr Keith Simpson, pathologist, gave evidence that in his view death took place a year or eighteen months before he saw the remains on July 18, 1942. Evidence in support of identification with the dead woman was given by Miss Mary Newman who is in charge of the photographic department at Guy's Hospital. She took a number of photographs of the remains and also made a picture of a photograph of the missing woman and on this superimposed a photograph of the skull. Evidence of identity was also given by a dentist. The prisoner was convicted. This is only the second case in which this photographic method of identifying human remains has been used. The first was in the Ruxton murder case in 1936, when it was introduced by two Scottish professors.

Vitamins for Expectant Mothers and Young Children

Concentrated orange juice from the United States is now available for all children up to the age of 5 years instead of 3 as heretofore. Cod liver oil compound was already available for children up to 5. Both products can now be obtained under the government scheme by expectant mothers during the last six months of pregnancy. But the minister of food states that only 24 per cent of the children eligible were getting cod liver oil and only 26 per cent were getting orange juice. The Ministry of Health including its dietitian Dr J. C. Drummond has therefore made an appeal to all parents to see that their children regularly take orange juice and cod liver oil. They can be obtained at local food offices and at 7,500 centers at a very low cost. A bottle of cod liver oil compound which lasts about six weeks costs only 20 cents and a bottle of orange juice equal to a dozen oranges and sufficient for a fortnight costs 10 cents. Those who cannot afford these charges can obtain both free.

Public Health in Bolivia

A decrease in the population and in the physical strength of the people who live in the eastern part of Bolivia has been observed for the last few years. A medical committee under the chairmanship of Dr. H. Kempis, head of the *Lucha Antiverminosa* of the Ministry of Public Health, was appointed by the government to investigate the causes of this situation. Medical examinations were made on 5,178 persons. It was learned that 99 per cent of the population of the region had helminthiasis, especially *asclostomiasis* and many had tuberculosis or malaria, leprosy, gonorrhea or syphilis. The committee found that improving the sanitary conditions of the villages and educating these people are problems of great importance. In almost all villages the supply of water is either insufficient in quantity or not well cared for. The ignorance and lack of individual and collective care are obvious. A tree called *higueron*, or *oge* which grows in large numbers near the Beni river has anthelmintic powers. Also numerous plants from which pyrethrum is obtained have antihelmintic powers.

Antituberculosis Campaign in 1941

Dr. Alejandro A. Ramondi, director of the Municipal Center of Buenos Aires for a Campaign against Tuberculosis has published a report of work done by the center in 1941. There were 2,708 deaths from tuberculosis in Buenos Aires in that year. Tuberculosis in the city has increased because of the number of patients from the provinces who come to the city. The routine practice of taking roentgenograms of children has resulted in finding early tuberculosis in unsuspected children and also in preventing the spread of the disease. The roentgen examination of the chest of apparently normal persons gave good results. Tuberculosis was found in 5 cases (13 per cent) of a group of 384 students (who had a roentgen examination of the chest in the Instituto Municipal de Tuberculosis) and in 25 cases (3.02 per cent) in a group of 826 applicants for municipal positions.

Brief Items

In Argentina a law was recently passed which established an honorary committee to conduct a crusade against *echinococcosis*. The committee is formed of physicians and veterinarians. It depends on the Ministry of Agriculture and the National Department of Hygiene.

The Pan American members of the Instituto Internacional de Protección a la Infancia with headquarters in Montevideo met the last week of August in Montevideo. Dr. Gregorio Arioz Alfaro, the Argentine representative of the council of the institute, was president of the reunion. Miss Elizabeth Shirley Enoch of Washington was the representative of the Children's Bureau of the United States.

The Asociación Congresos de Cirugía comprising representatives of medicine and surgery in Bolivia, Brazil, Chile, Paraguay, Argentina and Uruguay, resolved to meet for the first Congress of Surgery in Buenos Aires. The Asociación Argentina de Cirugía gave the preference to the University of Santiago the fourth centennial of the foundation of which is celebrated this year. The congress is to be held in Santiago on November 14-19 to discuss acute peritonitis, fractures of the humeral diaphysis and nontuberculous purulent pleuritis. The address of the headquarters of the general secretariat office of the association is Santa Fe 1171, Buenos Aires.

The Asociación Argentina de Dermatología y Sifilología recently held a meeting in Buenos Aires to celebrate the fiftieth anniversary of the foundation of the chair of dermatology in the Faculty of Medicine of Buenos Aires. Delegates from

South American countries were present. It was recalled that Dr. Baldomero Sommer was the first regular professor of the chair, which he occupied until his death in 1918. Dr. Maximiliano Aberastury occupied the chair from 1918 to 1925, when he retired. Dr. Pedro L. Balbina has occupied the chair since 1925. During the meeting, dermatologic sections were held with the collaboration of the delegates from South American countries. The advisability of forming a Latin American federation for the study of dermatovenereologic diseases and also a committee for studies on massive arsenotherapy was emphasized.

The association emphasized the importance of intensifying the crusade against leprosy in Argentina. The association also voted to establish scholarships for the interchange of dermatologists who work in clinics in various countries of the American Hemisphere.

Personals

Dr. Juan P. Garrido of Buenos Aires was appointed to the chair of pediatrics and puericulture at the Faculty of Medicine of Buenos Aires to fill the vacancy left by Dr. Mamerto Acuña who retired, having reached the age limit. Dr. Garrido is the author of "*Medicina Infantil*" of which more than seventeen thousand copies have been published. He has written books on tuberculosis in childhood, rickets and vitamin K and is the editor of the *Archivos Argentinos de Pediatría*.—Dr. Alfredo V. Di Cio won the Mariano R. Castex prize, which is given by the Academia Nacional de Medicina of Buenos Aires and the premio al mejor trabajo which is given by the Faculty of Medical Sciences of Buenos Aires for his book "*Enfermedades de los arterias perifericas*".—Drs. Egidio S. Mazzei and Jorge M. Remolín won the Doctor Luis Agote prize for their book "*Estudio clinicoradiológico del enfisema pulmonar*". Dr. Mazzei previously was awarded prizes of the Faculties of Medicine of Paris, Brazil and Buenos Aires for clinical studies on pneumothorax and primary bronchopulmonary tumors.—Dr. Frank Norman Wilson of the University of Michigan Medical School recently delivered lectures at the Faculty of Medicine of Buenos Aires and the National Academy of Medicine.—Dr. Fred H. Albee of New York accepted the invitation which Dr. Oscar Kaimowitz, head of the Instituto de Quirúrgica extendió to him to come to Buenos Aires for the inauguration of the ward of orthopedics of the institute which is named the Dr. Albee ward.—Dr. Jose Aree, ex-dean of the Faculty of Medical Sciences of Buenos Aires, is in the United States visiting scientific centers to study the organization of centers of hemotherapy.

Marriages

SIDNEY RICHARD KALISKI, San Antonio, Texas, to Miss Sophie Faverin at Albuquerque, N. M., December 4.

HUBERT BENJAMIN HAYWOOD, JR., Raleigh, N. C., to Miss Virginia Louise Allison of Richmond, Va., October 17.

FREDERICK SMITH DIER, Williamsport, Pa., to Miss Ethel Warring of Allenwood in Tampa, Fla., September 15.

CLAUDE NASH HERNDON, JR., Winston-Salem, N. C., to Miss Margaret Forester Caldwell of Greensboro, October 10.

JAMES FRANCIS ZACARIA, St. Paul, to Miss Marie Filomena Scialletta at Kansas City, Mo., October 10.

HOWARD BAILEY WILLIAMS to Mrs. Betty Carlson Lide, both of Birmingham, Ala., in November.

PAUL W. VAN METRE to Mrs. Lucy Hinton, both of Rockwell City, Iowa, October 11.

VIVIAN ALLISON TENNEY to Mr. John Franklin Bover, both of New York, November 29.

BEN A. DREIBRODT, San Antonio, Texas, to Rita Legliart of Pittsburgh, November 25.

BEATY LEE BASS, Lenoir, N. C., to Miss Patsy Smith of Winston-Salem, recently.

Deaths

George Washington Crile ♂ world renowned surgeon, died January 7 at the Cleveland Clinic aged 78 of subacute bacterial endocarditis.

Dr Crile was born in Chili, Ohio Nov. 11, 1864. He graduated at Ohio Northern University and in 1887 at the University of Wooster Medical Department, Cleveland, now Western Reserve University School of Medicine. Early in his career Dr Crile studied in Vienna, London and Paris. He served at Wooster University first as lecturer and demonstrator in histology and later as professor of physiology and professor of the principles and practice of surgery. He was professor of clinical surgery at Western Reserve University from 1900 to 1911 and professor of surgery from 1911 to 1924. He was also director of research at the Cleveland Clinic Foundation, of which in 1921 he was a cofounder.

Research conducted by Dr Crile included the basic factors concerned in circulation, respiration, blood chemistry and the body's source of energy. He was perhaps first to make a direct blood transfusion performed in 1905.

Dr Crile was awarded the Alvarenga prize by the College of Physicians of Philadelphia in 1901, the Cartwright prize by Columbia University in 1897 and 1903, the Senn prize by the American Medical Association in 1898, the *American Medicine* medal for service to humanity in 1914, the National Institute Society Sciences medal in 1917 and the Trumble Lecture medal in 1921. In 1925 the Lannelongue International Medal of Surgery was presented to him by the Société internationale de chirurgie de Paris, in 1931 the Cleveland medal for public service and in 1940 the distinguished service gold key of the American Congress of Physical Therapy.

The memberships in scientific societies of Dr Crile included among others the American Association of Anatomists, the American Association for the Advancement of Science, American Association for the Study of Goiter, American Physiological Society, American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Southern Surgical Association, Southern Medical Association, American Philosophical Society, American Association of Pathologists and Bacteriologists, Society of Clinical Surgery, Society of Experimental Biology and Medicine, National Institute of Social Sciences, National Research Council, Association for the Study of Internal Secretions, American Heart Association, American Medical Editors' Association, Ohio State Medical Association, Cleveland Academy of Medicine, Cleveland Medical Library Association and the Inter-State Postgraduate Medical Association of North America, of which he was chairman of the program committee. He was a member of the founders' group of the American Board of Surgery. In 1923 he served as president of the American Surgical Association.

A member of the board of regents of the American College of Surgeons since 1913, Dr Crile was chairman of the board from 1917 to 1939 and president of the college in 1916. In 1907 he was Third Vice President of the American Medical Association and chairman of its Section on Surgery, 1910-1911. He was also an honorary or corresponding fellow or member of many American and European societies.

In 1898 Dr Crile was brigade surgeon in the volunteers with the rank of major, serving in Cuba and Puerto Rico. He was a major in the Officers' Reserve Corps, and professional director of the U. S. Army Base Hospital number 4, Lakeside Unit (British Expeditionary Force number 9) in service in France for one year beginning May 1917, subsequently serving as senior

consultant in surgical research, lieutenant colonel and in November 1918 colonel. He was brigadier general in the Medical Officers Reserve Corps in 1921, holding the same rank in the auxiliary reserve corps since 1929. In 1919 he was awarded the Distinguished Service Medal and in the same year became an honorary member of the Military Division third class, Companion of Bath (British). In 1922 he was made a Chevalier in the French Legion of Honor.

Dr Crile was a prolific contributor to scientific literature. Among numerous articles and textbooks are *Surgical Shock* 1897, *Surgery of Respiratory System* 1899, *Certain Problems Relating to Surgical Operations* 1901, *On the Blood Pressure in Surgery* 1903, *Hemorrhage and Transfusion*, 1909, *Anemia and Resuscitation* 1914, *Anoci-Association (with Lower)* 1914, second edition *Surgical Shock and the Shockless Operation Through Anoci-Association* 1920, *Origin and Nature of the Emotions* 1915, *A Mechanistic View of War and Peace* 1915, *Man an Adaptive Mechanism* 1916, *The Kinetic Drive* 1916, *The Fallacy of the German State Philosophy* 1918, *A Physical Interpretation of Shock Exhaustion and Restoration* 1921, *The Thyroid Gland (with others)* 1922, *Notes on Military Surgery* 1924, *A Bipolar Theory of Living Processes* 1926, *Problems in Surgery*, 1928, *Diagnosis and Treatment of Diseases of the Thyroid Gland (with others)* 1932, *Diseases Peculiar to Civilized Man* 1934, *The Phenomena of Life*, 1936, *The Surgical Treatment of Hypertension* 1938, and *Intelligence, Power and Personality* 1941.

Dr Crile's contributions to experimental work through the years resulted in many improvements in surgery and medical practice. He traveled widely, his charm and his forceful personality marked him for leadership early in his career. The contributions of his active and curious mind are a lasting monument.

Jabez Henry Elliott, Toronto, Ont., Canada, University of Toronto Faculty of Medicine 1897, associate in medicine and clinical medicine at his alma mater from 1909 to 1931 and since then professor of the history of medicine, president of the American Association of the History of Medicine member and past president of the American Clinical and Climatological Association, past president of the Canadian Association of Tuberculosis, fellow of the American College of Physicians and in 1923 vice president, fellow of the Ontario Medical Association and in 1904 vice president, fellow of the Academy of Medicine of Toronto and in 1920 president, fellow of the Royal

College of Physicians of Canada, the College of Physicians and Surgeons of Ontario, the Ontario Historical Society and the British Medical Association. In 1934 was elected president of the Canadian Military Institute which he served as librarian for many years, a founder of the National Tuberculosis Association, physician in charge of the Muskoka Cottage Sanatorium from 1898 to 1907. During World War I served in the medical corps of the Canadian Army for many years, chief of diseases of the chest at St. Michael's Hospital and associate physician at the Hospital for Sick Children. In 1900 went to Nigeria as a member of an expedition studying malaria and other diseases. Ontario representative on the editorial board of the *Canadian Medical Association Journal* aged 69 died December 18.

Ewing Wilber Day, Provincetown, Mass., Georgetown University School of Medicine, Washington, D. C. 1889, member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Otolaryngology, member and past president of the American Otolaryngological Society, Inc., member, president in 1908 and treasurer from 1901 to 1907 and from 1909 to 1937 of the American Laryngological, Rhinological and Otolaryngological Society, past president of the Allegheny County Medical Society, a founder and past president

In 1934 was elected president of the Canadian Military Institute which he served as librarian for many years, a founder of the National Tuberculosis Association, physician in charge of the Muskoka Cottage Sanatorium from 1898 to 1907, during World War I served in the medical corps of the Canadian Army, for many years chief of diseases of the chest at St. Michael's Hospital and associate physician at the Hospital for Sick Children. In 1900 went to Nigeria as a member of an expedition studying malaria and other diseases. Ontario representative on the editorial board of the *Canadian Medical Association Journal*, aged 69, died December 18.

Ewing Wilber Day, Provincetown, Mass., Georgetown University School of Medicine, Washington, D. C., 1889, member of the Medical Society of the State of Pennsylvania and the American Academy of Ophthalmology and Otolaryngology, member and past president of the American Otolological Society, Inc., member, president in 1908 and treasurer from 1901 to 1907 and from 1909 to 1937 of the American Laryngological, Rhinological and Otolological Society, past president of the Allegheny County Medical Society, a founder and past president

GEORGE WASHINGTON CRILE, M.D., 1864-1943

of the Pittsburgh Academy of Medicine fellow of the American College of Surgeons, for many years professor of otology, laryngology and rhinology at the University of Pittsburgh School of Medicine where he had been professor emeritus since 1928, a founder of the Pittsburgh Eye and Ear Hospital and its chief of staff from 1908 to 1928 consultant, St. Margaret Memorial and Children's hospitals, Pittsburgh, and the Columbia Hospital, Wilkensburg, specialist certified by the American Board of Otolaryngology, lieutenant colonel in the medical reserve corps of the U. S. Army not on active duty served as a major and lieutenant colonel in the medical corps of the U. S. Army during World War I, aged 80, died, November 24, in the Doctors Hospital, New York.

Henry Erdmann Radasch, Philadelphia, Jefferson Medical College of Philadelphia 1901, appointed professor of histology and embryology in the department of anatomy on Nov. 20, 1922 and on June 15, 1942 became emeritus professor of histology and embryology at his alma mater, where he had been demonstrator of histology and embryology from 1901 to 1903, associate from 1903 to 1918 and associate professor from 1918 to 1922, instructor of histology at the Pennsylvania College of Dental Surgery from 1906 to 1909 and adjunct professor of physiology, pathology and bacteriology 1909-1910, instructor in anatomy at the Pennsylvania Academy of Fine Arts from 1913 to 1918, histologist at the Philadelphia General Hospital in 1920, member of the American Association of Anatomists, author of *Manual of Anatomy*, "A Compend of Histology" and "A Manual of Histology" contributed fifteen articles to the Reference Handbook of the Medical Sciences, aged 68, died November 29 of coronary occlusion.

Alfred Baker Spalding, San Francisco, Columbia University College of Physicians and Surgeons, New York 1900, appointed instructor in obstetrics at the University of California Medical School in 1902 and in 1909 professor of obstetrics, became professor of obstetrics and gynecology at the Stanford University School of Medicine in 1912 and in 1934 professor emeritus, member of the House of Delegates of the American Medical Association in 1917-1919 and 1923, member of the California Medical Association, the Pacific Coast Surgical Association and of the Pacific Coast Society of Obstetrics and Gynecology, honorary fellow in 1933 of the American Gynecological Society, specialist certified by the American Board of Obstetrics and Gynecology, the director of San Francisco Maternity from 1904 to 1915, consultant in gynecology and obstetrics at San Francisco Hospital and Stanford University Hospitals until 1933, aged 68, died November 26.

Albert Allemann, Takoma Park, Md., George Washington University School of Medicine, Washington, D. C., 1904, retired at the end of February, 1942 from active duty in the library of the Surgeon General's Office where he had been since 1900, was for fifteen years principal assistant librarian and editor of the *Index Catalogue*, at one time assistant editor of the *Index Medicus* and later on the staff of the *Quarterly Cumulative Index Medicus*, will be remembered for his editing, on the *Index Catalogue* including four volumes of the second and all of the third series, aged 82, died December 10.

Henry Willard Allen, Ridgefield, Conn., Medical-Chirurgical College of Philadelphia, 1909, author of *Diseases of the Rectum*, aged 65, died recently.

Raymond C. Almy, Auburn, N. Y., Syracuse University College of Medicine 1908, member of the Medical Society of the State of New York, coroner of Cayuga County, aged 60, on the consulting staff and formerly president of staff of the Auburn City Hospital, where he died, November 29.

Marvin Armstrong, Merkel, Texas, Medical Department of Tulane University of Louisiana, New Orleans 1892, member of the State Medical Association of Texas for thirty-five years, surgeon for the Missouri, Kansas and Texas Railroad, aged 76, died, November 27, in a hospital at Fort Worth of complications as the result of injuries received in a fall.

Robert Anderson Bennett, Riverdale, Md., George Washington University School of Medicine, Washington, D. C., 1906, past president of the Prince Georges County Medical Society, for many years medical examiner for Prince Georges County and health officer for Riverdale, one of the founders and director of the Citizens Bank of Riverdale, aged 80, died November 11.

Urban Clark Billingsley, Hayward, Calif., Cooper Medical College, San Francisco, 1904, aged 67, died, November 15.

Sigmund F. Braunfield, New York, Long Island College Hospital, Brooklyn 1919, aged 51, died, November 22, in

the Manhattan General Hospital of cerebral hemorrhage and thrombosis.

Betha Portis Brindley, Danville, Ala., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1892, aged 87, died, November 29, in the Benevolent Society Hospital, Decatur, of pneumonia.

Sara Craig Buckley, Le Roy, N. Y., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884, at one time a medical missionary in Japan, aged 84, died, November 24.

Luther Grow Bunker, Waterville, Maine, Medical School of Maine, Portland, 1892, served twelve years as a member of the Board of Registration of Medicine in Maine for six years served as city physician and as mayor in 1907 and 1908, in June 1942 was presented with a gold medal by the Maine Medical Association in recognition of his fifty years in the practice of medicine, aged 74, died, November 26.

Martin Francis Cashin, St. John's, Newfoundland, Canada, McGill University Faculty of Medicine, Montreal, Que., 1923, aged 43, died suddenly, November 5.

Oscar G. Cranford, Sasser, Ga., Baltimore Medical College 1892, member of the Medical Association of Georgia, aged 76, died, October 25, in a hospital at Moultrie.

Charles Clarence Davis, Essex, Conn., Yale University School of Medicine, New Haven 1907, on the staff of the Middlesex Hospital, Middletown, aged 58, died, November 26, of carcinoma of the liver.

George Hicks Davis, Hollidays Cove, W. Va., Baltimore Medical College 1905, member of the West Virginia State Medical Association, aged 66, died, November 20, of cerebral hemorrhage.

Hervie Alden Dobson, Madison, Wis., Columbian University Medical Department, Washington, D. C., 1876, Civil War veteran, aged 100, died, November 27.

Charles Russell Doynne, Albuquerque, N. M., University of Arkansas School of Medicine, Little Rock, 1911, member of the New Mexico Medical Society, at one time on the staff of the Southwestern Hospital for the Insane, Madison Ind. and the Longview State Hospital, Cincinnati, the Topeka (Kan.) State Hospital, the State Sanatorium for Tuberculosis, Norton, Kan., New Mexico State Hospital, Las Vegas, and the Arizona State Hospital, Phoenix, aged 54, was found dead, November 1, in a local hospital of a self-inflicted bullet wound.

William Casper Duke, Freedom, N. Y., Kentucky School of Medicine, Louisville 1888, Jefferson Medical College of Philadelphia 1893, for many years village health officer of Freedom, aged 84, died, November 11.

Samuel Walker Ellsworth, Quincy, Mass., Harvard Medical School, Boston 1896, member of the Massachusetts Medical Society, served during World War I, had served on the staffs of Quincy City Hospital, the Massachusetts Memorial and the City hospitals, Boston, aged 72, died, November 26.

Richard Austin Flynn, Belleville, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1923, aged 44, died, October 8.

Bernard Freedman, Los Angeles, University of California Medical School, San Francisco 1941, aged 26, died, October 8, of postoperative hemorrhage.

Roscoe S. Graves, Saco, Maine, Homeopathic Hospital, College, Cleveland 1883, aged 84, died, November 29, in the Trull Hospital, Biddeford, of chronic myocarditis, hypertension and uricemia.

Oscar Blin Hall, Warrensburg, Mo., University Medical College of Kansas City, Mo., 1898, aged 74, died recently.

Orlando S. Harmon, De Kalb, Mo., St. Louis College of Physicians and Surgeons 1892, aged 78, died, November 6, in the Smithville (Mo.) Community Hospital.

Homer Benton Harper, Barberton, Ohio, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, Chicago, 1906, member of the Ohio State Medical Association, on the staff of the Citizens Hospital, aged 69, was instantly killed in an automobile accident, November 14.

Wayne Adelbert Harris, Santa Ana, Calif., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, aged 61, died, November 25.

John Joseph Hayden, Worcester, Mass., Baltimore Medical College 1908, aged 62, died, November 26.

Fred Stanley Heimer, Unadilla, N. Y., Baltimore Medical College, 1910, member of the Medical Society of the State of New York, formerly a pharmacist, for many years health

officer, served as a captain in the medical corps of the U S Army during World War I, aged 61, died, November 27

Hiram A Hess, Ross Calif Barnes Medical College St Louis, 1897, aged 75 died November 13

Leander S Holcomb, Riverside, Calif, University of Louisville (Ky) Medical Department, 1893, aged 77, died, October 4

William Henry Hood, Reno, Nev, University of Michigan Department of Medicine and Surgery Ann Arbor 1886 member of the Nevada State Medical Association formerly surgeon for the Southern Pacific Railway, past president of the Pacific Association of Railway Surgeons was a director of the Farmers and Merchants Bank, aged 80 died November 29

James Manney Howard Jr * Passed Assistant Surgeon Lieutenant, U S Navy, retired, Kinston N C University of Virginia Department of Medicine Charlottesville, 1915, entered the medical corps of the U S Navy May 22, 1917 and retired Feb 15, 1922 for incapacity resulting from an incident of the service, served during World War I, aged 51, died, November 17, in the Parrott Memorial Hospital

Edward Raymond Stone Jr, Washington, D C Georgetown University School of Medicine, Washington, 1939 was commissioned a first lieutenant and later a captain in the Royal Army Medical Corps aged 29, was killed in action in the Middle East, November 1, while in front line duty with the attacking forces during the advance in Egypt

Randall Hutchinson, Los Angeles University of Pennsylvania Department of Medicine, Philadelphia, 1887, formerly professor of physical diagnosis at the University of Southern California College of Medicine, formerly served as a member of the consulting staff at the Children's Hospital, aged 82, died, November 12

Clarence Andrew Kelly, St Croix Falls Wis, Marquette University School of Medicine, Milwaukee, 1939, member of the State Medical Society of Wisconsin, on the staff of St Croix Falls Hospital aged 33 was accidentally killed while hunting deer on November 16

Maud Emilie Taft Kew, Keene N H Woman's Medical College of Pennsylvania, Philadelphia, 1900, aged 68, died, November 7, in Boston

Robert Bruce King, Newborough Ont, Canada, Trinity Medical College Toronto, 1893, died, October 17

William Andrew Lee * Fergus Falls, Minn Northwestern University Medical School, Chicago 1911, past president of the Park Region District Medical Society, served overseas in the medical corps of the U S Army during World War I, served as health officer of Fergus Falls and coroner of Otter Tail County aged 62, on the staff of St Luke's Hospital on the staff and formerly chief of staff of the George B Wright Memorial Hospital, where he died, November 22, of uremia and pyelonephritis

John McKiggan, Donkin, N S Canada Dalhousie University Faculty of Medicine, Halifax, 1921, aged 51, died recently

Robert Hopkin Paterson, Hamilton, Ont, Canada, University of Toronto Faculty of Medicine Toronto, 1908 served as a captain in the Canadian Army Medical Corps during World War I, since 1920 had been in charge of special clinical work for the department of health with headquarters at the General Hospital, aged 59, died suddenly, November 6

James William Prowell, Kansas, Okla, St Louis College of Physicians and Surgeons, 1896, county health physician for Delaware County served as a first lieutenant in the medical corps of the U S Army during World War I, at one time associated with the Indian Service in White Horse S D, aged 69 died, November 27, on state highway number 33 2 miles East of Salina

Ben L Reitman, Chicago American College of Medicine and Surgery Chicago, 1904 at one time instructor of surgical pathology at his alma mater author of "Second Oldest Profession A Study of the Prostitutes Business Manager" and Sister of the Road The Autobiography of Boxcar Bertha,

a colorful figure in Chicago for many years aged 63, died November 16 of coronary thrombosis

Winifred Brenda Reynolds, Stevensville, Mont Dalhousie University Faculty of Medicine, Halifax N S, Canada, 1900 aged 64, died October 5

George B Ribble * La Moure N D University of Minnesota College of Medicine and Surgery, Minneapolis 1901 past president of the Southern District Medical Society aged 64, died, October 20, of cardiac thrombosis

John Lewis Riggles, Washington D C Columbian University Medical Department, Washington 1900 formerly associate clinical professor of obstetrics at the Georgetown University School of Medicine at one time instructor in anatomy at his alma mater known as the George Washington University School of Medicine formerly dispensary physician at the Columbia Hospital for Women and had been in charge of the surgery dispensary at the George Washington University Hospital aged 65, died, December 8

Walter Alfred Sangster, Stouffville, Ont, Canada University of Toronto Faculty of Medicine 1889, aged 77, died October 8

Albert Lytleton Savage, Ventnor N J Jefferson Medical College of Philadelphia 1887, aged 85 died, October 15, of chronic prostatitis and acute nephritis

James C Shanks, Toronto, Ont, Canada McGill University Faculty of Medicine, Montreal, Que, 1881, aged 89, died, September 17

Robert Lee Smith, Melbourne, Ark (licensed in Arkansas in 1903), aged 66, died, November 17, of gout and uremia

Roy James Snider, Thessalon, Ont, Canada, University of Toronto Faculty of Medicine 1916 served during World War I with the Canadian Army Medical Corps as a lieutenant and later with the Royal Army Medical Corps as a captain, aged 50 died September 20

Joseph H Spicer, Cumberland, Md, Baltimore Medical College, 1910, aged 56 died, November 30, in the Memorial Hospital of chronic myocarditis

Harry Stein * Sandusky Ohio Syracuse University College of Medicine, 1930, aged 43 died November 7

Robert Mills Stephenson, Lexington Miss Atlanta (Ga) College of Physicians and Surgeons, 1908 member of the Mississippi State Medical Association fellow of the American College of Surgeons served during World War I on the staff of the Holmes County Community Hospital, aged 59 died November 26 of coronary thrombosis

Arthur Ellis Threlkeld, Wheatley Ky Chicago Homeopathic Medical College, 1880, member of the Kentucky State Medical Association, for many years chairman of the board of education of Wheatley, and bank president, aged 80 died November 21 of coronary sclerosis

William Massie Tunstall, Lovington, Va University of the City of New York Medical Department New York 1891, for many years chairman of the board of supervisors of Nelson County, aged 73, died, November 24

Clarence David Vrooman, Ellenville N Y, Albany Medical College 1892, member of the Medical Society of the State of New York, aged 82 on the staff of Benedictine Hospital Kingston, and of the Veterans Memorial Hospital where he died, November 24

William P Watson, Dyersburg, Tenn Memphis (Tenn) Hospital Medical College 1899, member of the Tennessee State Medical Association, past president of the Dyer-Lake-Crockett Counties Medical Society on the staff of the Baird-Brewer General Hospital aged 68, died, November 18 of carcinoma of the sigmoid with metastasis

Edward George Weadock, Lima, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900 member of the Ohio State Medical Association served overseas in the medical corps of the U S Army during World War I aged 66 died, November 22

James A Wright * Morrison, Ill, Beaumont Hospital Medical College, St Louis, 1887 aged 83, died, November 18

"VITAMINS FOR COLDS"

To the Editor.—In the article entitled "Vitamins for the Prevention of Colds" by Cowan Diehl and Baker, on page 1268 in the Dec 19, 1942 issue of THE JOURNAL, the following paragraph appeared: "Most of the studies for the prevention of colds have been limited to vitamin A alone or to vitamins A and D as contained in cod liver oil. The experiments with vitamin A have resulted almost uniformly in negative results, while cod liver oil has been reported by a number of authors to reduce the severity and by some the frequency of colds. Most of the latter reports, however, are based on inadequately controlled studies." Under footnote 1 appeared a reference to a paper by Drs Alfred F. Hess, J. M. Lewis and L. H. Barenberg entitled "Does Our Diet Require Vitamin A Supplement?" published in THE JOURNAL, Aug 26, 1933, page 657.

The implication, therefore, is that we expressed the opinion that cod liver oil reduced the severity or the incidence of respiratory infections and also that our study was inadequately controlled. We wish to call attention to the fact that our study was grossly misinterpreted by the aforementioned authors as first we found that cod liver oil or products containing vitamin A had no effect on the incidence or severity of respiratory infections and secondly we had observed eighty infants who received no vitamin A supplements and served as controls. These control infants were housed in a model child caring institution in the same wards as those who received vitamin A supplements.

In a previous communication (Barenberg, I. H. and Lewis, J. M. "Relationship of Vitamin A to Respiratory Infections in Infants" THE JOURNAL, Jan 16, 1932, p. 199) as well as in a subsequent report (Lewis, J. M., and Barenberg, L. H. "The Relationship of Vitamin A to the Health of Infants" *ibid* April 23, 1938, p. 1338) we also found that the addition of vitamin A to the average diet of infants had no beneficial effect on the incidence or severity of respiratory infections.

New York

"THE PSYCHIATRIC ASPECTS OF MARIHUANA INTOXICATION"

To the Editor.—In the September 1942 issue of the *American Journal of Psychiatry* there appeared a paper entitled "The Psychiatric Aspects of Marihuana Intoxication" by Drs Allentuck and Bowman. The paper contained certain observations which appear to be based on research conducted in New York City at Welfare Hospital under the auspices of the Mayor's Committee on Marihuana. In the Dec 5, 1942 issue of THE JOURNAL there appeared an editorial on the paper by Drs Allentuck and Bowman.

The research of Drs Allentuck and Bowman was made, it is true, on only 77 subjects, and those apparently were all drawn from a prison population. Nevertheless several of the conclusions reached confirmed information in our possession. Thus the indication that marihuana precipitates in certain persons psychoses and unstable and disorganized personality is in accord with findings already in our possession. The conclusions of the study, as Dr Kolb points out in his remarks on the paper (printed at the end of Allentuck and Bowman's paper in the *American Journal of Psychiatry*) certainly make it clear that use of marihuana may be an important contributory cause to crime. Drs Allentuck and Bowman state definitely that marihuana by relaxing inhibitions may permit antisocial tendencies to come to the fore.

Of course the primary interest of the Bureau of Narcotics is in the enforcement aspect. From that point of view we feel that it is very unfortunate that Drs Allentuck and Bowman should have stated so unqualifiedly that use of marihuana does not lead to physical, mental or moral degeneration and that no permanent deleterious effects from its continued use were observed. I am aware of course, that the *American Journal of Psychiatry* and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION are published for a select professional group of readers who will understand the statement for what it was, that is a scientific statement that certain phenomena were not observed in the study of a small group drawn from a prison population. More indiscriminating readers are perhaps likely to interpret the statement as the final word of the medical profession. Also there may well be some unsavory persons engaged in the illicit marihuana trade who will make use of the statement in pushing their dangerous traffic.

I am sure that you and most of your readers are familiar with the studies which have led to the conclusions that continued use of marihuana produces or is a contributing factor in mental disorders and physical deterioration. I have collected and attach quotations from a few sources which discuss the problems that arise from the use of marihuana.

The relationship between marihuana and hemp drug addiction has been worked out by us in some of the large mental hospitals (Chopra R. V. and Chopra C. S. "Present Position of Hemp Drug Addiction" memorandum Indian Medical Research Memoirs, supplementary series to *Indian Journal of Medical Research* July 1939).

There seems no doubt that cannibis is responsible for a proportion of the admissions to mental hospitals in the Union (Watt J. M. and Breyer Brandwijk Maria C. "The Datura Problem in South Africa" *South African M. J.* 10: 573 [Aug. 22] 1936).

It is proved beyond doubt that the prolonged use of Indian hemp usually leads to insanity. There is a special form of mental disease commonly met with in India which is produced by prolonged moderate use of hemp drugs in any form.

Prolonged use of large doses of hemp mixed with dhatura seed is responsible to some extent for unpremeditated murder, running, much grievous hurt etc. which occur daily in a vast country like India (Dharmapala J. F. "A Brief Review of the Types of Insanity Commonly Met with in India with a Full Description of Indian Hemp Insanity Peculiar to the Country" *J. Ment. Sc.* 76: 254 [April] 1930).

Indian hemp plays an important role in the greater part of mental disorders observed in the Mussulmans of the Regency. Chronic intoxication leads at length to insanity. The abuse of cannabis leads to insanity. Chronic (cannibis) intoxication is serious in that it leads at length to total loss of will power. Intellectual decadence is complete (Brotterus Perceval Haigh—Weed of Lolly and Dream *Indo. Vega* 1934).

We have a number of instances where the hemp drug habit has been so established in relation to insanity that admitting (as we must admit) that hemp drug is intoxicant causes more or less of cerebral stimulation it may be accepted as reasonably proved that hemp drugs do cause insanity (Report of Indian Hemp Drugs Commission 1893 1894).

The drift toward a chronic condition is very gradual. The subject becomes less and less fit for work. An inveterate addict lives in a state of permanent stupor. Eventually he has to be placed under restraint as the result of some crime or at any rate of act of violence. In serious cases of dementia due to hashish mental and organic collapse go hand in hand (League of Nations document O. C. 1542 [a] dated Geneva Feb. 17, 1937. Subcommittee on Cannibis of the Advisory Committee on Traffic in Opium and Other Dangerous Drugs. Report by Dr. J. Bouquet. Hospital Pharmacist, Tunis. Inspector of Pharmacies, Tunis, containing answers to the questionnaire submitted to the experts document O. C. 1542 [j]).

In visits paid by the writer to the Cairo Insane Asylum it was found that insanity was due to the inhalation of hashish by smoking (Church Archibald and Peterson Frederick. *Nervous and Mental Diseases*. Philadelphia W. B. Saunders Company 1908).

Continued use of the drug causes insanity in many cases (Kolb Lawrence. *Marihuana Federal Probation* publication of the Bureau of Prisons Department of Justice).

When used daily in large quantities the direct action on the cerebrum often causes chronic mental deterioration (Yavger A. S. "Marihuana—Our New Addiction Problem" *Am. J. M. Sc.* 195: 351 [March] 1935).

Hashish smoking gives rise to general physical deterioration (Lewin Louis. *Phantastic Narcotic and Stimulating Drugs Their Use and Abuse* New York E. P. Dutton & Co. 1931).

O'Shughnessy, medical director of Bengal Army in 1838 reported at least twelve eventual evil consequences of indulgence in cannibis (O'Shughnessy W. B. *On the Preparations of Indian Hemp or Cannabis* London 1838).

In certain circumstances hashish delirium has been seen to persist for several days and to assume disturbing proportions (Richey Charles. *Intellectual Poisons* Paris 1877).

With respect to the possible therapeutic applications of marihuana I strongly agree with Dr. Kolb that Dr. Allentuck and Dr. Bowman are there treading on exceedingly dangerous

ground. Certainly there is need of considerably more investigation before marihuana is used in attempted cures of morphine addicts. I take it from their paper that Drs. Allentuck and Bowman are fully aware of that need for further investigation.

H. J. ANSLINGER, Washington, D. C.
Commissioner of Narcotics

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
CHICAGO Feb. 15-16, 1943. Sec. Council on Medical Education and Hospitals. Dr. H. G. Weiskotten, 535 North Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL Jan. 9, page 148.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS, Parts I and II. Various centers. Jan. 20-22 and March 1-3. Exec. Sec., Mr. Everett S. Elwood, 225 S. Fifteenth St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF NEUROLOGICAL SURGERY. Chicago Feb. 13-16. Sec. R. Glen Spurling, 404 Brown Bldg., Louisville, Ky.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. Written Part I. Various centers Feb. 13. Candidates in military service may take Part I at their place of duty. Oral Part II. Pittsburgh May 19-25. Sec. Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY. Oral All Groups. Parts I and II. March 1. Sec. Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY. Oral. New York May or June. Final date for filing application is March 1. Sec. Dr. Dean M. Lierle, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PEDIATRICS. Starting July 1, 1943. Group I will be abolished. Sec. Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY. Detroit prior to the meeting of the American Psychiatric Association. Final date for filing application is March 1. Sec. Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF SURGERY. Part I. March 4. Final date for filing application is Jan. 25. Sec. Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

AMERICAN BOARD OF UROLOGY. Chicago Feb. 12-14. Sec. Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis.

Tennessee September Report

The Tennessee State Board of Medical Examiners reports the written examination for medical licensure held at Memphis Sept. 30-Oct. 3, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-seven candidates were examined, 20 of whom passed and 7 failed. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Georgetown University School of Medicine		(1938)	1
Howard University College of Medicine		(1942)	1
Northwestern University Medical School		(1941)	1
University of Tennessee College of Medicine		(1942-16)	16
Vanderbilt University School of Medicine		(1942)	1
School	FAILED	Year Grad	Number Failed
University of Tennessee College of Medicine		(1942-7)	7

Fifteen physicians were licensed to practice medicine by endorsement from August 19 through November 12. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
University of Alabama School of Medicine		(1900)	Alabama
College of Medical Evangelists	(1941)	N B M Ex	
Stanford University School of Medicine		(1935)	California
Emory University School of Medicine	(1932)	(1940)	Georgia
University of Illinois College of Medicine		(1941)	Illinois
University of Louisville School of Medicine		(1928)	Kentucky
Tulane University of Louisiana School of Medicine		(1938)	Georgia
Duke University School of Medicine		(1935)	N B M Ex
University of Cincinnati College of Medicine		(1931)	Ohio
Western Reserve University School of Medicine		(1911)	Ohio
Hahnemann Medical College and Hospital of Philadelphia		(1921)	Penna
University of Tennessee College of Medicine		(1942)	Mississippi
Medical College of Virginia		(1913)	Virginia

Arkansas November Report

The Arkansas State Board of Medical Examiners reports the written examination for medical licensure held at Little Rock Nov. 5, 1942. The examination covered 12 subjects. An average of 75 per cent was required to pass. One candidate was examined and passed. The following school was represented:

School	PASSED	Year Grad
University of Arkansas School of Medicine		(1941)

Five physicians were licensed to practice medicine by reciprocity from June 6 through Nov. 27, 1942. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Loyola University School of Medicine		(1942)	Illinois
Tulane University of Louisiana School of Medicine		(1931)	Louisiana
Johns Hopkins University School of Medicine		(1933)	Maryland
University of Tennessee College of Medicine	(1931)	(1941)	Tennessee

Hawaii July Report

The Board of Medical Examiners of Hawaii reports the written examination for medical licensure held at Honolulu July 13-16, 1942. The examination covered 10 subjects and included 80 questions. An average of 75 per cent was required to pass. Twelve candidates were examined, 10 of whom passed and 2 failed. Four physicians were licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
University of Southern California School of Medicine		(1942)	1
Loyola University School of Medicine		(1942)	1
Tufts College Medical School		(1941)	1
Creighton University School of Medicine		(1941)	1
New York University College of Medicine		(1937)	1
University of Rochester School of Medicine and Dentistry		(1931)	1
Hahnemann Medical College and Hospital of Philadelphia		(1939)	1
University of Pennsylvania School of Medicine	(1918)	(1939)	2
University of Wisconsin Medical School		(1936)	1

School	FAILED	Year Grad
Chicago Medical School		(1940)
Pennsylvania Medical School, Shanghai		(1936)

School	LICENSED BY ENDORSEMENT	Year Grad
University of Colorado School of Medicine		(1939)
George Washington University School of Medicine		(1936)
Harvard Medical School		(1938)
Cornell University Medical College		(1933)

South Carolina June Report

The State Board of Medical Examiners of South Carolina reports the written examination for medical licensure held at Columbia, June 22-24, 1942. The examination covered 17 subjects and included 50 questions. An average of 75 per cent was required to pass. Forty-six candidates were examined, all of whom passed. Seven physicians were licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Emory University School of Medicine		(1942)	1
Tulane University of Louisiana School of Medicine		(1942-4)	4
Jefferson Medical College of Philadelphia		(1942)	1
Medical College of the State of South Carolina		(1942-40)	40

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Atlanta College of Physicians and Surgeons		(1903)	Georgia
University of Georgia School of Medicine	(1938)	(1939)	Georgia
University of Louisville Medical Department		(1910)	Kentucky
New York Medical College and Flower Hospital		(1936)	Ohio
Duke University School of Medicine		(1937)	Penna
University of Nashville Medical Department		(1902)	Texas

School	LICENSED BY ENDORSEMENT	Year Grad
Boston University School of Medicine		(1939)

Rhode Island October Report

The Rhode Island Board of Examiners in medicine reports the written examination for medical licensure held at Providence, Oct. 1-2, 1942. The examination covered 10 subjects and included 73 questions. An average of 80 per cent was required to pass. Ten candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year (grad)	Number Passed
Tufts College Medical School	(1941)	(1941)*	2
St. Louis University School of Medicine		(1942)*	1
Syracuse University College of Medicine		(1921)	1
Jefferson Medical College of Philadelphia			
	(1940)	(1942)	4
University of Alberta Faculty of Medicine	(1941-2)	(1936)	1
Dalhousie University Faculty of Medicine		(1942)*	1

* Licenses have not been issued.

Colorado October Report

The Colorado State Board of Medical Examiners reports the written examination for medical licensure held at Denver, Oct. 7-9, 1942. The examination covered 8 subjects and included 63 questions. An average of 75 per cent was required to pass. Four candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year (grad)	Number Passed
University of Chicago		(1939)	1
The School of Medicine		(1921)	1
Deutsche Universität Medizinische Fakultät Prag

MEDICOLEGAL ABSTRACTS

Liability of Manufacturer or Distributor for Death Resulting from Inhalation of Carbon Tetrachloride Sold in Cans Not Labeled "Poison"—In the course of his employment over a period of about two months McClaren used a liquid solvent carbon tetrachloride, to remove grease from the inside of a boiler he was installing. On May 4, 1938 he worked from three to six hours inside the boiler's preheater, a cased-in box about 14 feet long, 8 feet high and 40 inches wide where the temperature was about 110°. During that time the solvent was kept inside the preheater in an open pan and the workman from time to time saturated a rag in the pan and 'sloshed' it around the inside of the preheater. He became ill that day, just when the reported case does not state, and three days later died from carbon tetrachloride poisoning. Subsequently the administratrix of his estate brought suit for his death against the defendant who had sold the carbon tetrachloride to the deceased's employer. From a judgment for the defendant, the administratrix appealed to the Supreme Court of Missouri, division No. 1.

The liability of the defendant was predicated on the negligent, so it was contended, failure of the defendant to label the containers in which the solvent was sold so as to indicate that the contents thereof were poisonous in alleged violation of an Illinois statute, the state in which the deceased was working which made it a criminal offense for a person to sell or deliver 'any arsenic, strychnine, corrosive sublimate, prussic acid or other substance usually denominated as poisonous, without having the word 'poison' affixed to its labels. Apparently, it was conceded that if the defendant in marketing the solvent had violated this statute he was admittedly negligent and there was a legal causation between his negligence and the death of the workman. While carbon tetrachloride was not specifically mentioned in the statute just referred to, the plaintiff contended that it was included within the phrase 'other substance usually denominated as poisonous.' In construing this statute, said the Supreme Court, so as to determine

whether or not the defendant was negligent we must resort to that familiar rule of construction known as the *eiusdem generis* rule. According to that rule, where a statute contains general words only, the general words must receive a general construction, but where the statute enumerates particular classes or things, followed by general words, the general words so used are to be construed as applicable only to things of the same general character as those which are specified. Thus, before the phrase 'or other substance usually denominated as poisons' can be construed to include carbon tetrachloride, we must be able to say that it is like some one of the species and kinds of poisons expressly mentioned in the statute. It could not do this, for in the court's opinion, carbon tetrachloride contains no single element of the various poisons enumerated by the statute. Obviously, carbon tetrachloride is not a drug but a grease solvent sold commercially as a cleaning fluid, and is not the same kind or class as the substances mentioned in the Illinois statute. The poisons there mentioned are of such character and universally so dispensed as to require a warning of their poisonous nature if taken internally in order to prevent a purchaser, or other person into whose hands the drug may come, from taking the same internally by mistake and to guard against overdoses of such as may be prescribed for medicinal purposes either alone in minute quantities or as an ingredient of a medicinal preparation. It follows, therefore, that in the light of the penal nature of this statute carbon tetrachloride is not plainly or necessarily included among its provisions and it was not negligence for the defendant to sell carbon tetrachloride without having the word 'poison' affixed on the label of the container. Nor do we think continued the court, that the administratrix has adduced any substantial evidence that the defendant negligently sold and delivered carbon tetrachloride in containers bearing no warning that its use might cause sickness or death. It appeared from the evidence that the carbon tetrachloride used by the workman had been taken from cans labeled 'Volatile Solvent use with adequate ventilation. Avoid prolonged breathing of vapor.' The evidence showed that there was no danger in using this product unless it was used in a confined unventilated place. Furthermore an agreed statement of facts showed that other manufacturers of carbon tetrachloride use a similar label in fact the label as used by the defendant had been adopted by manufacturers of this product and had been approved by the Surgeon General of the United States [sic] in 1934. No one is held by the law to a higher degree of care than the average in the trade or business in which he is engaged. *Keller v. Imour & Co.* 2 Cir. 247 F. 921, 100 Fed. 931, 1 R. A. 1918D, 798. A man in conducting his business in the way that everybody else in a like business does, has measured up to the standard demanded by the law and has exercised the ordinary care of prudent men engaged in the business.

The court therefore affirmed the judgment of the trial court in favor of the defendant—*McClaren v. G. S. Robins & Co.*, 162 S. W. 2d 856 (Mo. 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Acid Factor in Duodenal Ulcer—Berk, Thomas and Rehfuess studied the gastric and duodenal acidity of 7 dogs, 22 normal persons and 23 patients with duodenal ulcer. There were some nineteen thousand determinations of the gastric and duodenal contents simultaneously collected from areas just above (pars pylorica) and just below (duodenal bulb) the pylorus. They observed that the contents of the first part of the duodenum are endowed with a considerable capacity to neutralize, buffer and dilute gastric chyme which commonly exceeds the physiologic needs. Nevertheless, even in normal subjects the duodenal bulb is an acid area and free acid is not an abnormal observation. In patients with duodenal ulcer the neutralizing ability in the duodenal bulb is impaired but not wholly absent. Such patients appear to differ from normal persons in that the neutralizing capacity in the duodenal bulb and gastric hyperacidity are defective. The acidity of the contents of the duodenal bulb is largely determined by the type of food being digested and is only partially related to the degree of gastric acidity. The acidity in the stomach and duodenal bulb is not sharply parallel. None of the customary measures of gastric acidity reliably indicate the behavior of the effective acidity in the duodenal bulb at the same time. The usual oral therapeutic dose of antacids to patients with duodenal ulcer only slightly and transiently reduces the acidity of the contents of the first part of the duodenum, the reduction may be followed by a rebound increase. Neutralization of the contents of the duodenal bulb by fasting equals, and in some respects surpasses, that observed during digestion. This neutralization in normal man is exceeded by that in normal dogs. The acidity of the contents of the first part of the duodenum is generally insufficient to affect gastric motility significantly except in patients with duodenal ulcer. It may be a factor in stimulating pancreatic secretion.

Radium for Gastric Acidity—The effects of radium irradiation on the acidity of the gastric mucosa were studied by Jenkins and McGeorge. Fourteen patients with duodenal ulcer were treated with radium. In all, thirty tests of gastric function were carried out prior to radium treatment and forty-four after treatment. Thirteen of the 14 patients have had a decided reduction in acidity of the gastric juice and in the volume of juice secreted. Clinical improvement usually accompanied the chemical improvement.

Hemolysis—Miller, Singer and Dameshek determined the "hemolytic index" from an average of the output of urobilinogen in the feces in four days. This determination has proved of great value in the diagnosis and follow up of various blood dyscrasias particularly those associated with increased blood destruction. Since the daily fecal output of urobilinogen depends on the total mass of circulating hemoglobin, it is important to relate the former to the latter. This is done in the "hemolytic index," which shows that 111 to 208 mg of fecal urobilinogen is normally derived from 100 Gm of circulating hemoglobin in twenty-four hours. In anemia, or of a small surface area (as in children), the hemolytic index may show a greatly increased rate of blood destruction, although the absolute content of urobilinogen may be normal. This is particularly evident in certain types of hemolytic anemia and in pernicious anemia. In the latter a normal level of bilirubin in the blood with a greatly increased hemolytic index is common. The various indexes (acholuric jaundice, "indirect bilirubinemia, an increase in urinary excretion of urobilinogen, anemia and leukocytosis) of possibly increased hemolysis are not specific, but an increase in the fecal output of urobilinogen or in the hemolytic index is unequivocal evidence of an increased breakdown of blood.

Bacterial Endocarditis—The in vitro inhibitory effects of seven sulfonamide compounds on twenty organisms isolated from 17 patients suffering from bacterial endocarditis were correlated by Organ and Poston with the clinical bacteriostatic activity of these drugs in a series of thirty-three clinical (in vivo) experiments. A certain degree of correlation existed between the in vitro inhibitory effects of these drugs and their clinical bacteriostatic activity. This emphasizes the importance of preliminary in vitro experiments to determine the most effective drug against the freshly isolated organism and its possible clinical level of inhibitory action. It appears that the in vitro and the in vivo effects of the sulfonamides may be correlative.

Anthrax—Gold's experience with the treatment of 60 cases of external anthrax since the advent of sulfonamide compounds leads him to believe that these compounds are reliable and safe substitutes for serum and also that the drugs should be given preference. Fifty-one of his patients were employees of a local mill engaged in the manufacture of inner lining for which the basic raw material is goat hair imported from China and India. The other 9 patients lived close to the mill and had contact with the employees or the mill's products. Twenty-one patients

were treated with antianthrax serum, 1 died. To secure recovery, 200 to 2,200 cc of serum was administered intravenously. Neoparsphenamine, in addition to the serum, was of little or no benefit. Forty-two patients were treated with sulfonamides, 39 had excellent results, 1 patient became worse after intensive treatment with sulfapyridine and its sodium salt but recovered after large doses of antianthrax serum, neoparsphenamine and immunotransfusions. 1 failed to respond to adequate doses of sulfathiazole but recovered on serum therapy, and 1 was taken off the drug too soon and was given antianthrax serum instead with good results. Sulfapyridine was the most effective sulfonamide compound, next came sulfathiazole, then sulfadiazine. Since nausea and vomiting are frequent with sulfapyridine, sulfathiazole is the drug of choice at present. Large doses of sulfathiazole should be given until edema is controlled. If there is no response in three days, antianthrax serum should be used. The use of sulfonamide compounds materially shortens hospitalization and disability.

Postoperative Chylothorax.—A case of postoperative chylothorax is reported as the result of inadvertent section of the thoracic duct during a sympathectomy for hypertension. Sudden death occurred after intravenous administration of autogenous chyle. This Whitcomb and Scoville state, is the first time in their experience, as well as in the voluminous literature on the subject, that the thoracic duct was exposed and inadvertently torn during a sympathectomy for hypertension. The patient's extreme emaciation made her vulnerable. Delayed chylothorax occurred even though the thoracic duct had been doubly closed with four silver clips. The pressure of chyle within this duct is probably far greater than experimental work shows. The patient died promptly from what appeared to be anaphylactic shock. Necropsy was not permitted, and without it it is impossible to differentiate conclusively between anaphylaxis, fat embolism and a foreign protein reaction. Of the 6 cases reported in the literature in which infusion of autogenous chyle was instituted, 3 were fatal. Necessary precautions in the future should consist of a careful test for sensitivity followed by 5 to 10 cc of chyle intravenously with a delay of thirty minutes before the infusion proper is started, rejection of specimens containing globules more than 3 microns in diameter and a twenty-four hour culture of the chyle. If chyle fails to meet the aforementioned standards, plasma and emulsified fats with daily aspiration of the chyle, should be used instead. If chylothorax persists after one week of this regimen, phrenicectomy is indicated. Fat and protein should be infused early to prevent rapidly progressive emaciation.

Sodium Salts of Sulfonamide Compounds.—Fox demonstrated in dogs and mice that sodium salts of sulfathiazole and sulfadiazine are suitable for local use in wounds. To obtain more complete comparative data he determined the dissociation constants of sulfonamide compounds. It is noteworthy that in the body sulfathiazole and sulfadiazine are almost completely ionized, whereas sulfanilamide is but slightly ionized. The important fact is that since sulfadiazine and sulfathiazole occur

in the body largely in the ionized form and since their sodium salts are only moderately alkaline, resembling sodium bicarbonate, their local use seems worthy of trial. The experiments show that oral, local, peritoneal and clays administration of sulfadiazine gave similar blood levels. Therefore a given quantity of drug suitably administered by any of these routes is distributed similarly throughout the body. The major advantages of local therapy are an immediate high concentration of the drug in the involved area. This concentration is sustained for twenty-four to forty-eight or more hours while the implanted drug is being transferred continuously but completely from the limited local area into the general circulation. A relatively gradual attainment (and loss) of a maximal blood level occurs. Since the implanted drug is removed completely when a soluble derivative is used foreign body reaction at the local site does not occur. As sulfathiazole and sulfadiazine are extensively ionized at the pH of the blood and when ionized their solubility is vastly increased over that in water or any of the more common solvents it is suggested that fluid or semisolid preparations, including ointments, should be prepared from the sodium salts in aqueous and not only bases if high local drug concentrations are desired. Safe renal excretion would be insured by favoring sulfonamide salt formation by keeping the urine alkaline.

Simple Splint for Arm or Leg—Parcher describes the use of a board as a splint for the arm or leg when other splints are not available. The splint is made of plywood $\frac{3}{8}$ inch thick and $3\frac{1}{2}$ inches wide with an expanded head end. The splint consists of three sections 12, 24 and 36 inches in length, respectively. The two shorter sections are for the arm the longest one for the leg. The splint has double slots and bolts with wing nuts as a means for adjusting it quickly and firmly to different lengths and angles. The slots of the 12 inch section put across the slots of the longer 24 inch section and bolted permit adjustment for arm length. The broad headed end serves for fixation, as a spreader for traction, to prevent rotation of the extremity and for contact with the patient. To stabilize the splint fixation bands from holes in the head end cross over the shoulder and are tied under the opposite shoulder.

Carcinoma of Cervix—The data from 915 proved cases of carcinoma of the cervix treated at the Kelly Clinic between October 1927 and January 1936 are presented by Jones, who especially correlates the clinical stage of the disease irradiation dosage and curability. A detailed analysis of the results discloses, as have studies by others, that the clinical stage of the disease is of paramount importance in determining the prognosis. The study of the effect of dosage on prognosis indicates that with a technic using large amounts of radium it is exceedingly dangerous to give less than 3000 millicurie hours. The same tendency is evident from an analysis of the cases according to the clinical stage of the disease. Radium is administered by the broken dose technic usually at intervals of four weeks, a total dose of about 4,000 millicurie hours being administered. This dosage is applicable only with applicators and specific amounts of radon and cannot be compared with other methods. The broken dose technic is used because it aids in reducing preexisting cervical infections in the same way as preradium roentgen therapy, with the additional advantage that the cutaneous area available for irradiation is used for treatment directed primarily to the parametrium and iliac gland areas. Also there is a lessened incidence of troublesome proctitis with the broken dose method. The x-ray beam is directed toward the para-

metrium and iliac gland region of the side in question and not toward the midline. Pubic sacral, trochanteric and perineal ports are employed, and sometimes even two small ports for each of these areas. A dosage of 1500 to 2000 roentgens measured with scattering is given to each port. Therapy must not be withheld even in the absence of palpable disease of the parametrium. Sulfanilamide and sulfathiazole have been used locally to reduce cervical infection. Whether their use will improve salvage remains to be seen but they have been most helpful for combating infection.

Pyrexia and Roentgen Therapy—On the basis of gradually accumulating evidence Shoulders and his co-workers suggest that the maximal destructive effect of roentgen therapy on tumor cells should be obtained by applying it at the time of the greatest physiologic disturbance caused by induced fever which is also lethal to certain tumor cells. They subjected 50 patients with far advanced inoperable cancer to roentgen therapy while the hyperpyrexia was at its height. Once the desired elevation of temperature (104 to 106 F) is reached it is maintained for an hour. The patient fully protected by blankets is then transferred to a warm roentgen therapy room. The patient is kept well wrapped except for the portion of the body to be irradiated. The number of combined fever and roentgen treatments varied from one to four depending on the lesion and its location. Additional roentgen therapy alone has been administered to all patients. There have been no fatalities traceable to the technic used. Thirty-nine (78 per cent) of the patients have shown definite improvement such as relief of pain, decrease in the size of the tumor, cessation of hemorrhage, improved appetite and general comfort. The list in some instances suggests complete clinical relief. Eleven patients have shown no demonstrable improvement. The combined method of treatment produced results definitely superior to those obtained with irradiation alone. It is yet too early to indicate whether combined fever and roentgen therapy will be more than a palliative procedure. The procedure might serve as a more valuable adjunct to surgery than irradiation alone in cases in which postoperative irradiation is indicated.

Preoperative Use of Sulfathiazole—Since July 1940 Colston and Satterthwaite have administered one of the sulfonamide drugs for varying intervals of time preoperatively to every patient with infection of the urinary tract at the first examination or at operation if opening of the urinary tract was contemplated. The incidence of postoperative complications and morbidity appeared definitely reduced. A critical comparison of the postoperative course of patients so treated preoperatively and a control nontreated series, but having similar operations was undertaken. Of 110 treated preoperatively 39 had a temperature of 100 F or more on the first postoperative day, in 20 it was 100.5 F or more, in 14 101 F or more and in 3 it was 102 F or more. In the control group 87 of 196 had a temperature of 100 F or more, 57, 100.5 F or more, 40 101 F or more, 14 102 F or more, and 7, 102.5 F or more. On the second, third and fourth postoperative days the difference in the temperature of the two groups was essentially the same. Practically the same difference in respiratory infection and other postoperative morbidity existed in the treated and nontreated patients. There were no cases of pneumonia or bacteremia in the treated group as compared to 5 and 4, respectively, among the control patients.

Clinical and Biochemical Findings in Delayed Chloroform Poisoning M D Crawford —p 549

Prognosis in Carcinoma of Cervix—Gemmell treated 151 patients with carcinoma of the cervix between 1929 and 1938. In all but 2 the diagnosis was confirmed microscopically. In only 1 patient was Wertheim's hysterectomy performed; the rest were given radium and high voltage roentgen therapy. The technique of applying radium was that advocated by Heyman. All the patients were followed up to December 1940 or to the date of their death. Only 40 patients were alive at this time. More serious appearances in the bladder were associated with the more extensive stages of the disease. The survival rates of patients with transverse ridging or edema was roughly half that of patients with no changes or only minor changes in the bladder. The growth of the cancer toward the rectum is of serious prognostic import and affords some information of life expectancy. Variation of the dose of radium did not seem to affect the prognosis. Microscopic classification of the growth from the examination of material obtained by biopsy was of no assistance in determining prognosis. Patients who had a low value for the Bendien test before treatment usually had a significantly lower survival rate than those whose value was in the normal zone. The age of the patient or the number of children that she had at the time of treatment was no guide to the prognosis. The duration of symptoms prior to treatment was of no prognostic value. The prognosis in true stump carcinoma was approximately the same as when the whole uterus was intact. The prognosis was not affected when the disease appeared within two years of a pregnancy.

Erythroblastosis or Congenital Syphilis—During the last five years Henderson has encountered 53 infants with erythroblastosis. Nineteen of them recovered, 24 died and 10 were stillborn. In the present series 16 of the 46 mothers had 2, and 4 had 3 affected infants. First infants are seldom affected but once the disease has appeared in a family any subsequent infants are likely to be affected. There are four types of the disease: anemia hemolytica neonatorum, icterus gravis, hydrops fetalis and hepatic cirrhosis with intrauterine death and maceration. The fourth type is the worst type of erythroblastosis, although it seems to have escaped general recognition owing to the difficulties of obtaining macerated fetuses for examination. It seems probable that such fetuses with some edema have often been classified as having hydrops fetalis. Hydranmios during the last few weeks of pregnancy is common in this form of erythroblastosis, and intrauterine death is followed within a week or two by the delivery of a severely macerated fetus and the pale pink placenta is greatly enlarged, as in hydrops fetalis. There is little or no edema. The liver is slightly, if at all, enlarged and it is usually greenish brown, it is much less diffident than is expected from the degree of maceration. In syphilis the placenta is also pale pink with increased thickness and weight, but infarction, which is not a feature in erythroblastosis, is usually found in addition. In the placenta of this type of erythroblastosis a layer of Langhans' cells persists. This is the most characteristic microscopic feature. These cells normally disappear by the twenty-fourth week of pregnancy.

and their persistence to term is not known to occur in any other disease. The spleen is greatly enlarged. It is important to recognize this type of erythroblastosis and to differentiate it from congenital syphilis, which it superficially resembles. The records of 4 such cases are given.

Fate of Transfused Plasma—Beattie states that when plasma or serum transfusion is given normal human beings or experimental animals the pretransfusion blood volume is restored rapidly in some subjects and less rapidly in others. Transfusion of plasma with a normal plasma protein concentration after severe hemorrhage does not necessarily restore the blood volume to the normal value, even when the quantity of the plasma transfused is equal to or exceeds the total volume of blood lost. The increase in protein reserves which plasma transfusions bring about may be almost as important as the increase in blood volume. The drain on these reserves in severe infections and after extensive burns is obviously great, to support them may be as valuable as to combat bacterial invasion by sulfonamides. In shock the rate of plasma protein replacement is slow but as the plasma volume is increased the rate of replacement also increases. Movement of fluid into the blood stream takes place at rates, in man, of the order of 200 cc an hour. At the same time plasma proteins can enter at the average rates of about 15 Gm an hour. Such rates soon after hemorrhage may conceivably be much higher. On the other hand after transfusion fluid may leave the blood stream at rates of 100 cc a minute and plasma proteins at 4 to 6 Gm a minute. It is by no means clear how these massive movements are effected without ill results. The study shows that there is yet much to learn of the mechanisms involved in the control of plasma volume and mass movements of plasma protein.

Peripheral Vasoneuropathy After Chilling—Ungley and Blackwood give an account of 80 cases of 'immersion foot and hand' encountered in two and a half years in Scotland. The exposure or rather immersion lasted up to fourteen days. They suggest that the term 'immersion foot' is inaccurate and made quite as it does not include both the causative factor—cold—and the resulting neural and vascular disturbance, i.e. a peripheral vasoneuropathy after chilling. Judging from the patients' histories the following factors appear to influence the occurrence and the severity of the vasoneuropathy: time of exposure, temperature of water, immobility, body cooling, sickness, starvation, age, race (the dark-skinned races were more prone than the northern races), morale and treatment on rescue. The footwear afforded some protection during short exposure, but boots constricted the swelling feet and impaired the circulation during long exposure. There was no evidence that previous susceptibility to cold feet or chilblains was predisposing. Biopsy of interdigital nerves from two feet amputated two and a half and four months after exposure and of two lower limbs amputated four and eleven months after rescue showed almost complete wall-paper degeneration of the interdigital nerves and no significant vascular change. The tissues of the amputated limbs showed a persisting edema. The main nerve trunks showed severe degeneration and early regeneration, in the larger arteries there was slight intimal and medial fibrosis, in the large veins (1 case) patchy organized recanalized thrombi. The small vessels were not significantly abnormal. The muscles showed degenerative changes more severe than those following denervation. Probably injudicious warming of the affected limbs after rescue accentuates the damage by raising the metabolic demands of the tissues while they are still ischemic. For some hours after rescue affected limbs should be kept cool while the patients' bodies are being warmed. Once cold and wet have penetrated, boots should be discarded before they become tight. Active movements and postures impeding circulation should be avoided. Once rescued a man is stripped of wet clothing in a cool room and wrapped in blankets with the hands and feet exposed, and

he is given hot drinks. Massage is contraindicated. Patients are kept in bed, sometimes for many weeks, early walking may cause excoriation, blistering or increased swelling. The feet are raised on pillows, exposed to the air and kept dry. Sulfanilamide powder may be applied to wounds and blisters. Beneficial results from 'dry cooling' the hot hyperemic limbs with fans or ice bags are reported from Canada.

Febrile Reactions Among Smallpox Contacts—Febrile reactions occurred in 40 of 92 contacts received at a reception house for contacts during an outbreak of variola major in Glasgow. Of the 92 persons 22 were men, 28 women and 42 children less than 14 years of age. Fifty of the contacts had had close association with a smallpox patient for three to eight days, 27 had less intimate exposure and the contact of 15 was limited to one or two occasions. All contacts were vaccinated on the day of admission to the reception house, with success in 43, 29 who showed little or no response after several days were revaccinated successfully, and 20 were resistant to the vaccinia virus. A second vaccination appeared to activate the earlier one, which until then had shown no activity. The febrile reactions during the period of quarantine of 30 were clearly due to vaccinia and 2 to variola, 8 presented some difficulty in diagnosis. The onset of pyrexia varied between the sixth and thirteenth days after vaccination. Its duration was from one to three days. From a study of the fever of the 8 patients in whom it was difficult to classify, Napier and Insh conclude that 1. Smallpox may not be easy to recognize even in known contacts under constant observation. 2. Careful discrimination is required to decide whether the febrile attacks in contacts are due to vaccinia or to variola. 3. In a person who was recently vaccinated vaccinia is the most likely cause when the eruption is sparse but a few typical spots may be sufficient to indicate variola with certainty. 4. When vaccinia can be ruled out, a short febrile illness, with or without transient spots, that occurs in the second week after exposure offers presumptive evidence of variola.

New Method of Stimulating Gonadotropic Function of Pituitary—Barborka made the observation that 30 per cent of women who received a ketogenic diet acquired amenorrhea. Although Barborka remedied this condition by the administration

of vitamin B₁, Julesz is convinced that a hormone rather than a vitamin is involved because Hoffmann and Anselmino were able to isolate from the anterior lobe of the hypophysis a substance which increased the ketone bodies in the blood and was designated as the ketogenic hormone or the hormone of the fat metabolism. It is probable that the anterior pituitary plays a part in the development of ketosis and that in response to a ketogenic diet it elaborates the ketogenic hormone in increased quantities. The author investigated the question of whether ketosis stimulates only this or also other pituitary functions in mice and in human subjects. On the basis of his observations he considers it highly probable that ketosis stimulates the anterior pituitary to an increased production of the follicle stimulating principle and that any stimulus that is exerted on the anterior pituitary is probably also extended to the entire lobe. The author cites examples which indicate that the functions of the anterior pituitary do not change in an isolated manner. The ketogenic diet greatly stimulates the ketogenic hormone production but it also stimulates the gonadotropic hormone production. With the exception of roentgen rays the ketogenic diet is the only means of stimulating the anterior pituitary. In view of the fact that it increases the production of the follicle stimulating principle it is theoretically indicated in cases in which the gametokinetic function is to be increased. Thus it could be used in certain cases of azoospermia and in cases of hypofunction of the anterior pituitary such as hypophyseal dwarfism and infantilism and incipient Simmonds' disease. The ketogenic diet could be used for diagnostic and prognostic purposes.

*Trombidiosis (Harvest Itch) New Focus in Switzerland R. Schuppli —p 568

Trombidiosis New Focus in Switzerland—Schuppli reports that in July 1941 trombidiosis was observed for the first time in the region around Basel, Switzerland. A number of soldiers exhibited a severely itching exanthem in the axillae, on the articular flexor surfaces and about the hips. All the men who acquired the exanthem had picked bush beans. Investigation revealed red mites on the clothing and body of persons returning from the bean fields, and the same mites were discovered on the bean plants. They were identified as *Trombicula autumnalis*, or *Leptus autumnalis*. It is the larval form of the mite which causes the exanthem. The eruption is found on the covered parts of the body, particularly where the clothing adheres tightly. Shortly after a larva has attached itself to the skin, a red spot appears and becomes urticarial. An intensely itching papule develops which may have a small vesicle. Scratching ruptures the vesicles and crusts form. The scratching may result in secondary infection and pyoderma. The itching is extremely severe, intensified attacks occurring during the night. The papules persist for from ten to fourteen days. Two of about 100 soldiers were apparently immune and remained free from the exanthem in spite of exposure. The sudden appearance of trombidiosis in a region formerly free from it may be due to the introduction of the soy bean into this region. The treatment of trombidiosis is of minor importance, since it subsides spontaneously in about ten days. The itching can be counteracted by a menthol or zinc preparation. As a prophylactic measure the author suggests that the mites could be destroyed chemically while they are in the soil during the winter, or that the plants could be sprayed with insecticides. For the individual prophylaxis American authors recommend the use of sulfur on clothing and body. The author suggests application of a zinc preparation to the sites predisposed to attacks by the mites. Shower baths with generous soaping and change of clothing immediately after exposure may also prove helpful.

Dick's Reaction in Scarlet Fever A Invalidi —p 127
Infarct of Spermatheca Case in Infant A Brejer and A Colombo —p 149

Dick's Reaction in Scarlet Fever—Invalidi performed Dick's test on 150 children from 1 to 13 years of age with scarlet fever. The injection of toxin was systematically repeated with intervals of seven days. The test gave negative results in 113 of 141 patients who were brought to the hospital in the course of the first week of the disease in 4 of 5 patients who entered the hospital in the second week and in the 4 patients who were brought to the hospital on the third and fourth weeks of the disease. The author concludes that, according to his observations, the rate of negative results is 80 per cent. A negative reaction early at the beginning of the disease is negative all through it. Positive results of the reaction change to negative results in the third week of the disease in 50 per cent of the cases. Age, sex and complications of scarlet fever do not have any influence on the results of the reaction.

Pellagra in Adults—Alessandri and his associates report observations on 110 cases of pellagra which were observed in Santiago de Chile between 1934 and 1941. Pellagra exists in Chile in the endemic as well as in the alcoholic and secondary forms. Twenty-nine of the patients presented the endemic form, 60 the alcoholic form, in the remaining 21 it was secondary to some grave organic disorder. Alcoholism and organic disease were etiologic factors. Pellagra has been increasing during the last five years. The authors calculate that in recent years Chile must have had about 3,000 cases of pellagra annually. In the city of Santiago twice as many cases were of alcoholic as of endemic origin. Endemic pellagra was more frequent in rural than in urban regions, this is so in Chile as well as in other countries. Women developed the endemic form more often than men. Alcoholic pellagra was three times more frequent in urban than in rural environment and appeared almost exclusively in men. Pellagra developed most frequently in persons between the ages of 30 and 60 years. Hospitalization for pellagra increased during the four hot months of the year. The total mortality for pellagra was 26 per cent in the reviewed material. In alcoholic pellagra the mortality was twice as high as in endemic pellagra. The authors discuss three groups of symptoms: (1) cutaneous, (2) nervous and mental disturbances and (3) digestive disorders. Until the beginning of 1939 the authors treated their patients according to Goldberg's recommendations with bed rest, a diet rich in antipellagral foods and yeast. In some cases antianemic hepatotherapy was employed with vitamin B or A. Since 1939 nicotinic acid has been added to the aforementioned treatment. Excellent results were obtained with the classic treatment of Goldberg in the majority of cases, but in some cases of extreme malnutrition this treatment has failed. The introduction of nicotinic acid signifies a definite advance in antipellagral treatment. It greatly accelerates recuperation, shortens hospitalization and thus reduces the expense of the treatment. The nicotinic acid is not, however, a substitute for the dietetic treatment but rather an important complement.

Thrombopenic Purpura Caused by Sulfonamide Compound—Losada I and Fernandez W report the history of a man, aged 60, who was given daily 3 Gm of a sulfonamide compound for an injury to the left hand. Purpuric spots appeared on the fifth day of the treatment. There was a

generalized purpura, most severe on the face, thrombopenia, lack of retraction of the clot, bleeding time of more than ten minutes and positive Rumpel-Leede sign. Puncture of the bone marrow disclosed hyporegeneration and immature platelets. Purpura is one of the late manifestations of intolerance to sulfonamide compounds. In this case it appeared on the fifth day of the medication. This can be explained by the fact that a sulfonamide compound exerts a toxic effect on the hemopoiesis in the bone marrow and does not affect the cells in the circulating blood, so that these remain for several days their normal proportion, the symptoms appearing days after the first ingestion of the drug. The authors have observed 2 other cases of purpura after sulfonamide medication. In a case of pneumonia in which sulfapyridine had been given and the other a case of typhoid in which sulfaguanidine had been given. All 3 cases took a favorable course. The treatment of this complication consists in discontinuing the drug, administering large doses of vitamin C and daily transfusions of from 100 to 150 cc of blood.

Intensification of Corpus Luteum Action by Vitamin E in Treatment of Habitual Abortion—Bach and Winkler report observations on 127 cases of threatened abortion treated by them during the years between 1930 and 1941. In 32 cases abortion took place. The authors differentiate four groups according to the treatment employed. The first group of 74 cases remained untreated and in 24 of these abortion resulted. In the second group of 27 cases progesterone was given and in 5 of these the treatment failed. A third group of 10 cases was treated with vitamin E, in this group there was 1 failure. In a fourth group of 16 cases vitamin E and progesterone were given, in this group there were 2 failures. Administration of progesterone has the effect of a substitutional therapy for an insufficient corpus luteum. Vitamin E intensifies the function of the corpus luteum not only by increasing the progesterone effect but also by a true activation which is evidenced by the elimination of pregnandiol in the urine. The combined administration of vitamin E and progesterone unites the advantages of the two methods: the first doses of progesterone protect the pregnancy until the vitamin E can exert the intensifying effect on the corpus luteum generally for a period of three days. The authors advise that the treatment be initiated with 10 mg of progesterone, that this dose be reduced after three days and that it be broken off entirely after five days. The optimal daily dose of alpha tocopherol (vitamin E) is 30 mg. Lower doses activate the corpus luteum inadequately and only after a longer period. Doses in excess of 30 mg do not increase the efficacy. Threatened abortions in women with definite infantilism in whom the elimination values of pregnandiol indicate not only an insufficiency in the follicular apparatus but also of the corpus luteum cannot be averted by beginning treatment during pregnancy. The initial values of pregnandiol elimination are far below normal and the increase in function effected by alpha tocopherol is inadequate to maintain the pregnancy. The treatment to be successful in these cases must begin before the occurrence of pregnancy. Vitamin E is effective in increasing the production of progesterone and also in influencing growth of the fetus.

CORRECTION

Archiv fur Gewerbepathologie, Berlin—In the Current Medical Literature department of THE JOURNAL, January 2, page 86 the date of the issue of the foregoing German journal should have been April 16, 1941, instead of 1942.

Book Notices

New and Nonofficial Remedies 1942 Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1942. Austin E. Smith M.D. C.M. M.Sc. editor. Issued under the direction and supervision of the Council on Pharmacy and Chemistry of the American Medical Association. Cloth. Price \$1.50. Pp. 668. Chicago: American Medical Association, 1942.

Perhaps the most important feature of this year's New and Nonofficial Remedies is the radical rearrangement. This should make the contents more accessible and therefore more valuable to the reader. Heretofore the classification of products has been basically that of chemical relationship—the new arrangement is primarily according to therapeutic use, chemical classification being introduced by means of subheadings. In addition, the typographic style has been changed to give greater prominence to the products of individual manufacturers. Valuable features have not been sacrificed. The book still fulfils its function of establishing chemical standards for new and nonofficial preparations which the Council has found to be useful or to give adequate promise of usefulness in the treatment or prevention of disease. Its function as a guide to the most recent advances in therapeutics has been greatly enhanced.

Careful examination of the general discussions under the various headings and subheadings shows that the Council has performed its annual task of keeping the text abreast of the progress of medicine. The authoritative and compendious section of the sulfonamide compounds is an example. So also is the chapter on vitamins and vitamin preparations for prophylactic and therapeutic use. Equally important though less extensive revisions have been made in such sections as those on aluminum compounds, dextrose, gonadotropic substances, liver and stomach preparations, ovaries, parathyroid, pituitary and testes.

Among the newly accepted drugs are

Acetyl-Beta-Methylcholine and the proprietary brand, Mecholyl Chloride, proposed for use by iontophoresis, orally and subcutaneously as a parasympathetic stimulant.

Adrenal Cortex Extract for parenteral use in the treatment of Addison's disease or of adrenal insufficiency of other types as well as prophylactically in surgical procedures involving the adrenal cortex.

Aluminum Hydroxide Gel with the proprietary brand, Creamalin for oral use as an adjunct in the treatment of peptic (gastric and duodenal) ulcer.

Normal Human Serum and Normal Human Plasma

Others worthy of mention are

Cyclopropane, another general anesthetic, now included in the U. S. Pharmacopeia.

Amylcaine Hydrochloride, another proprietary local anesthetic. Pernoston Sodium, the sodium salt of the previously accepted proprietary barbitaric derivative, Pernoston.

This volume should be available to all medical students, physicians, pharmacists and others interested professionally or commercially in drug therapy. One cannot commend too highly the unselfish and untiring efforts of the Council on Pharmacy and Chemistry in the preparation of this invaluable contribution to rational and up to date therapeutics.

Drug Products Labeling Packaging Regulation By Arthur Donald Herrick. Member of the New York and Federal Bar. Fabrikoid. Price \$7.50. Pp. 462 with 7 illustrations. New York: Revere Publishing Company, 1942.

Mr. Herrick has made a worth-while contribution toward orienting for the average reader the problems relating to the interstate sale of drugs and their advertising. This book is one which will be useful not only to those who are interested in interstate drug commerce but to the members of the medical profession and allied sciences who have a natural curiosity in the control of drugs. The contents include discussions on the early and present history of federal drug legislation, the Federal Food and Drugs Act, the Federal Food, Drug and Cosmetic Act of 1938, the formation of the Food and Drug Administration products which are subject to the act, misbranded drug products, false and misleading labeling, packaged drug products,

informative labels, label display and prominence, adequate directions and warning against misuse, fraudulent and dangerous drug products, products exempt from labeling adulterated drug products, contaminated and harmful drug products, official drugs maintenance of nonofficial standards new drugs submission refusal and suspension of new drug applications and cosmetics. A valuable portion of the book is contained in the appendices, which include the Federal Food, Drug and Cosmetic Act general regulations relating to drug products U. S. Food and Drug Administration action on crude drugs and U. S. Food and Drug Administration methods of testing antiseptics and disinfectants. The material is presented in an easily read style and represents the type of information which should be made generally available in view of the ever increasing interest in the control of drugs.

Report of the Committee on Tuberculosis in War Time Medical Research Council, Special Report Series No. 246. Paper. Price 25 cents. 9d. Pp. 36. New York: British Information Service. London: His Majesty's Stationery Office, 1942.

Either the bovine or the human type of tubercle bacillus may give rise to disease in any part of the human body, and the type of infection can be determined only by careful bacteriologic examinations. In England and Wales, 98 to 99 per cent of all cases of pulmonary tuberculosis and 70 per cent of all cases of nonpulmonary tuberculosis are due to the human type of tubercle bacillus, and at all ages about 6 per cent of the deaths are due to the bovine type. In Scotland, however, the incidence of the bovine type of tuberculosis in man is higher than in England and Wales. Indeed, about 5 per cent of the cases of pulmonary tuberculosis are caused by the bovine type of tubercle bacillus. Because of the prevalence of both human and bovine tubercle bacilli in Great Britain, most persons come in contact with these organisms before they reach adult life and, therefore, practically all adults have at least the primary type of tuberculosis. Persons are liable to develop clinical tuberculosis either through fresh infections from the outside or from primary foci already established in their own bodies. Thus the situation in England varies definitely from that in the United States, where probably not more than 50 per cent of the entire population has been infected with tubercle bacilli and where in large areas this does not apply to more than 25 per cent. Moreover, in many parts of this country far more persons become infected in adult life than during childhood.

Tuberculosis mortality in Great Britain was gradually declining up to the beginning of the war. Indeed, between 1928 and 1938 the death rate in England and Wales was reduced from 91 to 60 per hundred thousand persons. Nevertheless in 1938, 230,000 cases of clinical tuberculosis were under supervision or the dispensaries of England, Wales and Scotland. That year 65,000 new cases and 30,000 deaths were reported. In 1941 there was an increase of about 10 per cent in respiratory tuberculosis over that of the immediate prewar years in England and Wales, and about 18 per cent in Scotland. For nonrespiratory tuberculosis the increase was 21 per cent for England and Wales and 28 per cent for Scotland. Thus, for all forms of tuberculosis the increased mortality was 13 per cent, or 3,780 actual deaths. In England and Wales the increase in respiratory tuberculosis affected mainly children, older men and younger women. However, the actual number of additional deaths among children has been much smaller than among adults in the case of respiratory tuberculosis.

The striking feature of nonrespiratory tuberculosis has been the increased incidence of tuberculous meningitis, which has affected all age groups up to 45. In children up to 10 years there has been a relative increase in mortality of 50 per cent.

While there were more actual deaths from tuberculosis during the first two years of the last war, the increase in mortality was 5 per cent for males and 7 per cent for females from 1914 to 1916, whereas in this war from 1939 to 1941 the increase has been 11 per cent for males and 13 per cent for females. During the last war children did not suffer appreciatively more from tuberculosis than in peacetime.

The authors call attention to the decline in mortality in Great Britain during the past eighty years. The lapse which occurred during 1914 to 1918 was thought to be due at that time to

unfavorable hygienic conditions, defective nutrition and increased industrialization. They believe that the greater prevalence of sources of human tuberculous infection has an important influence. Many tuberculous hospitals and sanatoriums were evacuated in September 1939 to make room for expected air raid casualties. Thus large numbers of patients returned to their homes while the disease was contagious. Blackout conditions, with diminished ventilation and increase in cross infection, overcrowding in homes due to destruction of residential property by enemy action and the added effects of billeting, evacuation of the population which may have led to billeting in homes containing infective tuberculous persons, and also the introduction of tuberculous persons into healthy homes, are thought to have played an important part in spreading tuberculosis. The evacuation of town populations to the country, with the result that many children previously supplied with pasteurized milk were then supplied with raw milk, is also considered significant. Therefore all ages of the population are being subjected to an increased risk of exposure to tuberculosis.

Apparently large numbers of persons working in factories have been exposed to fellow workers with contagious tuberculosis, since the demand for more labor has brought into activity many persons who in peacetime would not be working.

The following measures for the prevention of further increase in tuberculosis are discussed. The first consideration in this respect is to reduce the spread of bovine infection from dairy products. Tuberculosis is widespread among the cattle of Great Britain. Before the present war began about 40 per cent reacted to tuberculin, and 40 per cent of those slaughtered in the abattoirs had areas of disease sufficiently large to be seen with the naked eye. Five-tenths per cent of milch cows were eliminating tubercle bacilli through the milk. Over 6 per cent of all farms were sending out milk containing living tubercle bacilli. In 1937 the Ministry of Agriculture introduced a plan for controlling tuberculosis in cattle, but by 1939 only about 3 per cent of the dairy farms had their herds attested. Unfortunately, this plan had to be practically abandoned during the war and there seems no hope that further progress in the eradication of tuberculous infection from cattle can be expected until more normal conditions are restored. Therefore the milk will continue to contain tubercle bacilli and the only possible immediate solution is to destroy them by heat. The authors give various suggestions for pasteurization in towns and cities and educating housewives elsewhere to heat milk adequately.

The unsuspected case of tuberculosis is regarded as a significant factor in the increase of the disease during the present war. Symptoms usually appear late, and therefore most patients have moderately or far advanced disease when it is diagnosed. The authors believe that these unsuspected cases should be screened from those sections of the population where there is the greatest danger of spreading disease. For this purpose they recommend mass radiography. They feel that the miniature film is the best solution of the present problem because of the extremely low cost and the speed with which it can be processed. However, they are thoroughly cognizant of the fact that this is not the ideal method of doing x-ray work nor is it the fastest. They recommend mass radiography as a preemployment procedure and one which should be extended to all persons employed in certain industries. They also believe it should be a periodic requirement because they are cognizant of the fact that persons whose chest films may be clear on first examination may at any subsequent time present evidence of disease.

In administering the proper treatment of persons with tuberculosis the authors lament the fact that the number of beds in sanatoriums has been decreased and that nurses and physicians are difficult to obtain for the care of the tuberculous. All this adds significantly to the problem.

Some American workers will take issue with the statement that the risk of infection with tuberculosis from nursing tuberculous patients in sanatoriums is no greater than that involved in general hospital nursing.

The committee recommends a plan whereby the patient is allowed sufficient financial support for himself and his family until he is able to resume his work. It recommends a number of schemes for providing work for persons with the disease in

a quiescent noninfectious stage on a part time basis. It also calls attention to an extremely important special group, namely persons with chronic contagious tuberculosis who cannot be treated so as to render them noncontagious and yet are not seriously ill. Many of them have good working capacity either on a part time or a full time basis. It is believed that these persons could be employed in groups where they will not disseminate their tubercle bacilli to others.

The section on tuberculosis in institutions for the mentally ill is intensely interesting and throws further light on the real cause of the increase in tuberculosis during wartime. In peacetime the mortality rates from tuberculosis in these institutions was eight or nine times that of the general population. Between 1910 and 1914 it varied between 15 and 17 per thousand resident patients but during the last war it rose to 37 per thousand in 1917, and 52 per thousand in 1918. A similar trend is already apparent in the present war, and this applies also to the institutions for mental deficiency. During the last war it was thought that the increased mortality was largely due to insufficient diet, but the authors are not prepared to pass the same judgment now, because both the quantity and the quality of the food has been good in these institutions in this war. On the other hand, there has been definite overcrowding, which has apparently increased infection possibilities from contagious cases.

A concise summary of findings and recommendations by the members of the council is included. The report contains an unusually modern point of view on tuberculosis control which is applicable to any nation where nearly all of the adult population is infected with tubercle bacilli.

Ultra Violet Light and Its Applications Including a Description of the Numerous Practical Applications Found for Ultraviolet Light and Fluorescence in the Industries, Sciences and Arts. By H. C. Dake and Jack De Vent. Cloth. Price \$3.25. Pp. 209 with illustrations. Brooklyn & New York: Chemical Publishing Company Inc. 1942.

This volume deals largely with the utilization of ultraviolet radiation in commercial and technical applications. One chapter is devoted to medical sciences, and it stresses the employment of ultraviolet radiation in diagnostic procedures. Little or nothing is written on therapeutic applications of ultraviolet radiation. There are many clever ideas suggested for using ultraviolet radiation in the practice of surgery, bacteriology, dermatology and pharmacology. How diseased tissues will fluoresce in the presence of ultraviolet is described, and valuable hints are advanced for the technique of recognizing pathologic tissues. The significance of ultraviolet radiation in bacteriology utilizing microinjections of fluorescent dyes and the colors certain organic and inorganic chemical compounds will produce under the influence of ultraviolet radiation are described. At least half of the book is devoted to the uses of ultraviolet radiation in criminology and police science, military, advertising, theatrical, mining and oil drilling applications. A list of firms is recorded at which supplies may be obtained for use in ultraviolet and fluorescent practice.

Clinical Thermometers: A Recorded Voluntary Standard of the Trade. Commercial Standard CS1 42. U. S. Department of Commerce. Jesse H. Jones, Secretary. National Bureau of Standards. Lyman J. Briggs, Director. Third edition. Paper. Price 10 cents. Pp. 19. Washington: U. S. Dept. of Commerce, Printing Office. 1942.

This pamphlet describes approved methods for testing clinical thermometers. The National Bureau of Standards in 1927 was requested by a committee of the Associated Thermometers Manufacturers to assist in establishing a commercial standard for clinical thermometers, to encourage the production and sale of reliable thermometers and to protect purchasers from inferior and unreliable instruments. The proposed standards were drafted and adopted in 1928. The first revision was in 1931 and the second revision in 1940. In order to be accepted, thermometers must meet standards of construction, aging, pigment tests and tests for entrapped gas and accuracy. There are tests for "hard shakers" and for "retreating index." For the accuracy test, thermometers are compared at 98, 102 and 106 F and must be tested in a certain prescribed way as explained in the pamphlet. Rigid tolerances of accuracy are demanded. The bureau is to be congratulated for its efforts in assuring accurate thermometers for the profession.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DERMATITIS FROM CUTTING OILS

To the Editor—The matter of dermatoses in men in munitions factories working with water soluble oils becomes an acute one. In a certain factory there is in use a preventive Steridol number 3, made by the C B Dolge Company of Bridgeport Conn. Will you give me information concerning this product and about the matter of these dermatoses and the pertaining bibliography?
M D, Michigan

ANSWER—The large majority of cutting oil dermatitis occurs from the insoluble cutting oils yet these are sterile as far as pathogenic bacteria are concerned. Only a comparatively small percentage of dermatitis from cutting oils is caused by the water soluble cutting oils which, in contradistinction to the insoluble oils, usually contain many pathogenic bacteria. Usually they also have an offensive odor and may contain metal shivers. It is possible to have the skin injured by the shivers and the cut become infected from the bacteria in the water soluble oil or on the soiled skin and clothing.

Sedimentation and filtration to remove the chips and pasteurization to kill the bacteria are used in many plants where the water soluble oils are reclaimed and circulated through a sterilization system. In plants where pasteurization systems are not installed, antiseptics can be used in order to destroy the bacteria in soluble cutting oils.

Steridol number 3, sold by the Dolge Company, is one of these antiseptics. The extract composition of Steridol is not given by the manufacturers, but it is believed to be of the formaldehyde type of disinfectants.

The advantage claimed for disinfectants in cutting oils over heat sterilization is that when disinfectants are used the oil cannot be reinfected in the pipes and at the machines. The disadvantage of disinfectants is that they are all skin irritants and increase the dermatitis hazard from the cutting oils. Especially is this so because the continued addition of disinfectants to cutting oils for the purpose either of disinfecting them or of destroying or masking the objectionable odors (caused by the formation of sulfur compounds) has been known in some instances to increase the disinfectant content of such oils to as high as 5 per cent.

The claims made for Steridol can be read in a booklet entitled "Cutting Oil Sanitation," issued by the C B Dolge Company, Westport, Conn. For further reference to this subject see "Dermatitis from Cutting Oils" by Louis Schwartz (*Pub Health Rep* 56 1947 [Oct 3] 1941, reprint 2321).

ANATOMY OF LEFT PLEURAL CAVITY

To the Editor—In answer to M D, Utah (*The Journal*, May 9 1942, p 232), there appears the following statement: "The left pleural cavity largely drains via the vena azygos minor which usually empties into the left innominate vein and so is not so immediately obstructed as is the vena azygos major. According to all recent textbooks of anatomy in the English language (Piersol ninth edition 1930 p 895 Morris, ninth edition 1933 pp 735 736 Cunningham seventh edition, 1937 p 1241 Gray twenty second edition, 1930 p 668) and personal observations both vena azygos minor inferior and vena azygos minor superior empty into the vena azygos major. The left superior or highest intercostal vein which drains the blood from the upper three or four intercostal spaces, opens into the left innominate vein. The left superior intercostal vein often communicates with the left vena azygos minor superior and may drain a small amount of blood from the highest part of the parietal pleura on that side. The statement from *The Journal* quoted does not seem to agree with the anatomic findings therefore it should not go unchallenged."

K S Chouke M D, Philadelphia

ANSWER—The challenge to the statement in *THE JOURNAL* concerning the preponderance of right hydrothorax in congestive heart failure is well taken and indicates the need of elucidation. There should be a correction of the statement to read as follows: "Drainage from the left pleural cavity is by way of the hemiazygos (azygos minor inferior) and accessory hemiazygos (azygos minor superior) veins, the latter not only emptying into the vena azygos major but also anastomosing almost always with the left innominate vein, which connection may account for the lesser degree of venous obstruction on the left side than on the right."

DIFFERENTIAL DIAGNOSIS OF BACKACHE

To the Editor—I am 32 years old well nourished weigh 164 pounds (74 Kg) am 5 feet 8 inches (173 cm) tall and have suffered from flat feet for the last fourteen years. From the beginning I have had good medical care with regard to my arches. However I have always had trouble with my arch supports which for the most part were made of aluminum covered with leather. On the average I had new ones made every one or two years at the same time I had to go back to the orthopedic mechanic constantly for adjustments for they never felt completely satisfactory. Nevertheless I managed to get by somehow through a one year internship from 1937 to 1938, despite the fact that at this time my assisting in the operating room gave me sacroiliac backaches. During this time I saw many orthopedic surgeons. Exactly one year ago I decided to move my office from New Jersey to upstate New York. During this period I was busy packing and lifting heavy packages cartons and the like. After I had my work almost completed I suffered a sudden attack of upper back pain dull not radiating in the middle at the height of the seventh to tenth dorsal vertebrae. A well trained orthopedic surgeon ordered me to have a few days of bed rest after which I received a series of treatments which consisted of diathermy and massages of my back. I also exercised at home to straighten my posture and to increase my muscle tonus which is rather flabby because of the fact that I never had much of a chance to indulge in sports. My backaches were improved for a short time only to return again and for the last ten months I have never been without backache for more than a period of four or five days then they always recur. I have consulted several orthopedic specialists without any success. My backaches always improve temporarily after my back is massaged. For this reason I had no roentgenograms taken. Please advise me of the possible diagnosis and treatment and mainly please give me the names of a few authorities in this field preferably in the East.
M D New York

ANSWER—A differential diagnosis of backache such as described could not be made without additional information. Chronic malposture may result, in time, in producing symptoms of strain or wear and tear arthritis in the articular facets of the spine. Degenerative changes in the intervertebral disks secondary to an old healed vertebral epiphysitis are occasionally seen and are most often present in the lower thoracic spine. Herniation of an intervertebral disk may result from a lifting strain such as that which has been described.

Roentgenograms of the spine should be made. A careful neurologic examination is important. A therapeutic test of support by means of a good back brace may be helpful. As a number of competent orthopedic surgeons have already been consulted, it would appear to be advisable that a consultation should be arranged between an able orthopedic specialist and a neurologist. Perhaps a spinal puncture would be found to be indicated.

There is no one leading authority in this particular field in the big Eastern cities who is preeminently superior to other good orthopedic surgeons in the same locations.

POSTPARTUM CARE

To the Editor—Will you give me the current opinion regarding (1) the routine use of shock blocks following delivery, (2) postpartum laxatives for the mother and (3) the use of ergat or a similar preparation for the first twenty four to seventy-two hours post partum?
R F DeWitt M D, Plymouth, N H

ANSWER—1 There is no indication for the routine use of shock blocks following normal delivery. This is one of the procedures that should be reserved for the patient who has had excessive loss of blood.

2 Almost all mothers need a mild laxative following delivery, although there has been much abuse in the use of laxatives. For the patient who has had a natural delivery without perineal repair, liquid petrolatum can be started on the second day and if necessary a small tap water enema can be administered the third morning. The liquid petrolatum can be continued while the patient is in bed or an agar in oil preparation can be substituted. If the patient does not have a bowel movement, the small tap water enema can be repeated every other day. For the patient who has had an episiotomy, oil can be started on the second day and in the absence of a bowel movement the tap water enema can be administered on the morning of the fourth day. For the patient who has sustained an injury to the anal sphincter, the administration of liquid petrolatum can begin on the fourth morning, a small oil retention enema can be given the evening of the fifth day, and if there is no bowel movement this can be followed by a small tap water enema the following morning. This routine has provided satisfactory results in a large obstetric service.

3 It is the practice in many large institutions to administer a 0.2 mg tablet of ergonovine two or three times a day during the first seventy-two hours to all patients. Severe after-pains may warrant discontinuing the oxytocic drug. In the presence of infection or retarded uterine involution from some other cause, ergonovine can be continued for a longer period.

EPINEPHRINE AND PROCAINE SOLUTIONS IN DENTAL SURGERY

To the Editor—Several misinterpretations appear in reply to the query concerning the addition of epinephrine to the procaine solution used in dental operations (The Journal Sept 19, 1942, p 248). Dentists seldom employ epinephrine for the purpose of securing a dry field, if they should their success would be indifferent. While it appears that procaine hydrochloride alone is an adequate anesthetic for the surgical manipulation of soft tissues it is unquestionable that anesthesia of far greater depth is required to eliminate sensation in the parodontal tissues and especially the dental pulp. Experience has repeatedly shown that this is rarely secured without the addition of a vasoconstrictor which functions chiefly to intensify the action of the procaine by retarding its absorption. This becomes increasingly true in employing the nerve blocking method which is mandatory in anesthetizing the lower posterior teeth. Satisfactory operating results in these areas virtually never follow the use of procaine alone. Optimum effects require a concentration greater than 1.75,000 of epinephrine greater than 1.80 of procaine hydrochloride as well as a waiting period of over ten minutes to allow anesthesia to reach a satisfactory depth. Many thousands of patients with ankylosis syndromes have been injected with 2 to 3 cc. of such concentrations both in the hospital and in the dental office without encountering severe reactions if the principle of basal anesthesia with barbiturates is employed and the solution is injected extremely slowly with the patient supine. Moderate reactions may occur, as they do in other groups of patients but they are generally transitory and negligible. Nevertheless caution dictates that glyceryl trinitrate and other restoratives are at hand to anticipate an emergency. The answer to the problem posed would seem to be that the patient who is a poor risk for the anesthetic is likewise a poor risk for the extraction. Excepting for the relief of intractable pain the operation should be postponed until the clinical condition offers a proper margin of safety or perhaps be altogether avoided by compromise treatment. Even under favorable circumstances extraction is a procedure not devoid of hazards and should be approached with the same careful judgment as any other operative measure.

Leo Stern D.D.S., New York

To the Editor—In Queries and Minor Notes in The Journal Sept 19, 1942, page 248, there is a question about the use of procaine hydrochloride with and without epinephrine when dealing with the ankylosis syndrome. In the reply it is stated that either epinephrine is omitted in certain cases or cobefrin is used in place of it. It should be noted that clinical and experimental evidence shows that cobefrin is subject to the same disadvantages as epinephrine.

Isaac Neuwirth, New York

Associate professor of
pharmacology and therapeutics
New York University College of Dentistry

ANSWER—[These two letters were referred to the consultant who replied to the original query. His reply follows.] I still believe that the original answer is correct. It could have been amplified to include the effect of preliminary medication skill in injection, the patient's disability, his nervousness and his output of epinephrine, but brevity was indicated. I generally employ cobefrin in a dilution of 1:50,000 as compared to epinephrine in a dilution of 1:150,000. Epinephrine in this dilution causes constriction of peripheral blood vessels and thus produces a fairly dry field.

Under these conditions, obviously, absorption of the anesthetic solution is slowed and anesthetic solution is not lost by hemorrhage. Therefore anesthesia is considerably prolonged. Nevertheless, I see fewer untoward effects with cobefrin than with epinephrine and, under the conditions with which this correspondence deals, I prefer cobefrin.

DIETHYLSTILBESTROL AND HAIR LOSS

To the Editor—Can diethylstilbestrol cause the loss of hair from the scalp? A woman aged 22 never had a period previous to December 1941. She had bilateral mumps at the age of 10. The uterus was small, the breasts were infantile in type and there was a definite masculine hirsutism. With diethylstilbestrol which she has been taking since December 1941, periods have been at regular intervals and the dose of diethylstilbestrol has been regulated so as to have the periods at intervals of four weeks. The monthly dose was 1 mg. daily for five days and 2 mg. daily for another five days. In July she felt much better and I had not seen her again for three months. She still feels well but has skipped the last two periods. Practically all evidence of masculine hirsutism has disappeared and the scalp is noticeably bald especially in the region of the temples. I have noticed changes in the distribution of hair (possibly coincidental) with other estrogens but nothing so severe. The basal metabolic rate was minus 11 per cent in February. The blood pressure was 160 mm. systolic (following the death of a relative) but has now been normal since April. An organic basis for the blood pressure could not be found from pyelogram and urine cultures. The urea clearance test was normal.

M.D., Massachusetts

ANSWER—As far as is known there is no connection whatever between the loss of the hair from the scalp and the ingestion of diethylstilbestrol. The condition in the case cited would appear to be coincidental.

SYMPATHETIC AND PARASYMPATHETIC NERVE SUPPLY OF CEREBRAL VESSELS

To the Editor—Would you please inform me whether stimulation of the sympathetic nerves leading to brain vessels produces vasoconstriction or vasodilatation? Have any sympathetic vasodilator nerves in the cerebral vessels ever been found? Can acetylcholine act on the cerebral blood vessels producing vasodilatation and if so where does the acetylcholine develop, since there are no parasympathetic fibers present?

M.D., New York

ANSWER—Stimulation of one cervical sympathetic trunk produces feeble constriction of the pial blood vessels on the same side of the brain. Other nerve fibers reach the arteries of the brain stem from the facial nerve by way of the greater superficial petrosal branch. The last mentioned group of fibers are commonly referred to as parasympathetic. Stimulation of this group gives feeble dilatation of the blood vessels of the ipsilateral cerebral cortex. Acetylcholine produces moderate dilatation of the pial vessels. It may be assumed to develop at the so-called parasympathetic endings. In reality, the presence of parasympathetic vasodilator nerves has never been satisfactorily proved. It is probable that sympathetic nerves normally control both the constriction and the dilatation of blood vessels. It is true that stimulation of the peripheral ends of divided posterior nerve roots produces vasodilatation. This may be an abnormal antidromic effect releasing a chemical mediator at the sensory nerve ending on the blood vessel.

BIOLOGICALLY FALSE SEROLOGIC TESTS

To the Editor—A white woman aged 30 in excellent health presented herself for a routine blood test. She is unmarried and denies any possible exposure to syphilis by sexual intercourse. Physical examination and history are negative for symptoms and signs ordinarily attributed to a syphilitic infection. The history is extremely reliable in this instance. There is no history of previous infection or treatment for syphilis. A spinal fluid test has not been done.

Results of the Blood Tests

Date	Laboratory	Kline	Kahn	Kolmer	Kahn Verification Test
6 25 42	1	Positive	Neg	2+	Not done
7 2 42	1	Positive	Neg	2+	Not done
7 6 42	1	3+	±	Negative	Not done
7 6 42	2	Not done	Neg	Not done	Negative
7 6 42	3	Not done	±	Negative	
Eagle Mazzini done by this laboratory were negative Hinton was doubtful					
8 11 42	1	Not done	Neg	4+	Not done
10 3 42	1	Not done	Neg	Negative	Not done
10 16 42	1	Not done	Atypical reaction	Negative	Not done

This patient is now under my supervision. No antisyphilitic treatment has been given. Suggestions on the handling and further study of this case will be appreciated.

Don V. Hutton M.D. Fayetteville W. Va.

ANSWER—The conflicting serologic reports obtained thus far in this case do not warrant a diagnosis of syphilis and appear to be of the so-called biologically false positive type. The things that make these reports appear to be "false positive" are the inconsistency in the positive tests by different techniques, the variation in the degree of positiveness and the variation in the tests done on the same specimen of blood by three different laboratories. In view of these findings, a diagnosis of syphilis is not justified and accordingly treatment of this young woman for the disease is not warranted. A spinal fluid examination should be made because a positive report will sometimes be found even though the tests of the blood are as conflicting as in this case. If the spinal tests are negative, the future procedure would be to recheck the tests at two to three month intervals and when so doing to reexamine the patient for evidence of syphilis. It is not uncommon that false positive tests will spontaneously revert to negative and remain so when rechecking of the tests is done over a period of a year or so. If the spinal reports are positive, treatment for syphilis would then be warranted.

Numerous factors enter into the creating of the false positive test, among which are recent influenza infections, low grade febrile conditions, glandular tuberculosis, disseminated lupus erythematosus, past vaccination against smallpox, typhoid and drawing the specimen during the menstrual period. These are among some of the more recently found causes for unsatisfactory serologic tests such as the example given.

CONTINUOUS CAUDAL ANALGESIA IN OBSTETRICS

ROBERT A. HINGSON, M.D.

Passed Assistant Surgeon United States Public Health Service
AND

WALDO B. EDWARDS, M.D.

Passed Assistant Surgeon United States Public Health Service
STATEN ISLAND, N. Y.

Continuous caudal analgesia was developed to relieve the pains of labor and delivery. Since its beginning,¹ we have sought to improve our apparatus and refine our technic in order to provide the maximum of comfort for the mother with a minimum of risk for her and the baby.

Both Drs. J. B. De Lee and J. Whitridge Williams recognized that some obstetricians would literally follow the Biblical injunction "in sorrow shalt thou bring forth" but stated that it was the duty of the obstetrician to mitigate the sufferings of natural labor and delivery. They demanded that any anesthetic, analgesic or anesthetic agent possess safety for mother and child.

Since 1847, when Sir James Y. Simpson introduced ether in obstetrics, there has been a continuous search for a perfect method. Many different agents, used either alone or in combinations, have been described for this purpose. Not one has been found that completely meets the postulated criteria without at the same time altering the normal mechanism of labor.

Sicard² and Cathelin, working independently, blocked the sacral and coccygeal nerves through the sacral hiatus. They found in 1901 that fluids when injected into the peridural space by this route rise to a height in direct proportion to the amount of preparation used and the speed with which it is forced into the canal. Cathelin further showed that when sufficient cocaine was injected into the sacral canal of the dog it resulted in complete anesthesia of the entire body.³

Laewen and Gaza in 1911 and Schlumpert⁴ in 1913 used caudal anesthesia in Germany for obstetric cases. In America the technic has been used successfully by Meeker and Bonar in 1923, others followed. Oldham in 1925, Lundy in 1928, Henry and Jaur in 1929, Rucker in 1930, Campbell in 1935, Johnson in 1936

and Sword in 1936.⁵ In 1939 Baptista⁶ reported the successful use of caudal anesthesia in 200 obstetric cases. Lahmann and Mietus⁵ in January 1942 reported 400 obstetric cases in which caudal anesthesia was used.

These investigators confirm the practical usefulness of caudal block for delivery with comparative safety for both mother and child. Most of the writers cited described a satisfactory anesthesia resulting from an introduction of from 30 to 40 cc of 1 or 2 per cent solution of procaine or metycaine into the extradural space of the sacral canal. Most found the duration of this anesthesia to be between forty minutes and an hour and a half.

We have sought to modify their methods so that the analgesia could be started in the early stages of labor to relieve the pain and discomfort for the parturient in this period with the added advantage of continuing this analgesia until the completion of labor and postpartum repair.

In a previous paper we wrote that we used this procedure in obstetrics only after it had been thoroughly studied in the management of twenty surgical operations on the perineum and lower extremities. We first used it in our surgical service, working with Southworth,⁷ in October 1941 for a bilateral phlebectomy. Since that time we have managed the entire course of six hundred labors and deliveries with this method without resorting to any other form of anesthesia. We believe that continuous caudal analgesia has opened a new medical horizon to the profession comparable to that developed by Lemmon and Paschal⁸ with continuous spinal anesthesia. However, we would emphasize that with our method the drug producing the analgesia is continuously bathing the nerve trunks of the sacral and lumbar plexuses within the peridural space. At no time does this medication enter the subdural space of the spinal canal. Consequently the patient is still able to move the lower extremities throughout labor, and uterine contractions continue without impediment.⁹

THE NERVE SUPPLY TO THE UTERUS

Our solution of the problem of the relief of pain during labor and delivery has been the use of a continuous regional nerve block of both the somatic and autonomic pathways which transmit the pain impulses. At the same time we have endeavored not to interfere with the motor nerve fibers to the uterus and the

nerves to the accessory skeletal muscles which have a part in the voluntary expulsion of the baby. This we have designated continuous caudal analgesia.

Head¹⁰ in 1893 postulated that the pain impulses of labor were transmitted through the lower thoracic and upper lumbar sympathetic ganglions. Cleland¹¹ in 1933 located these pathways in the human being by clinical observations following paravertebral sympathetic nerve block as coursing through the ganglions of the eleventh and twelfth thoracic segments. In more than 600 case studies we have substantiated these contentions. We have tested the level of skin analgesia in every patient receiving the caudal block. We have found that it is necessary to extend this level of analgesia up to and including the area supplied by the eleventh thoracic nerve and the iliohypogastric nerve on both sides before the patient has complete relief from labor pains. The superior extent of this area lies midway between the umbilicus and the pubis. Whenever the analgesia of the skin falls below this area on either side there is return of the sensations of abdominal cramps on that side, with the intensity increasing as the level of analgesia descends.

Sherrington, Head, De Lee, Rucker¹² and Cleland have contended that the motor nerve supply to the

cervix and lower uterine segment and that they carry pain fibers from these areas and the upper portion of the vaginal vault. There is some suggestion that they also carry inhibitory fibers to the uterus by innervating the longitudinal muscle fibers of this organ. Prolonged block of these nerves through continuous caudal analgesia produces definite softening of the cervix with more rapid effacement of the lower uterine segment and cervical dilatation as determined by rectal examinations.

Thus from this clinical study it would appear that the autonomic nerve supply to the uterus may be divided into the components presented in the accompanying tabulation.

In substantiating this work on cadavers we studied the dissection made of the peridural space in sixty cadavers after 30 cc of methylene blue solution had been injected through the sacral hiatus. We found that in no case did this injection go higher than the sixth thoracic segment but always as high as the tenth dorsal segment. In many of them we found the structures more intensely stained on one side and to a higher level than on the other.¹³

Thus our dosage tables were calculated both by neurologic studies on women in labor and by dissection studies on necropsy material. We sought to determine the required volume of solution necessary to reach the pain fibers without paralyzing other vital nervous functions.

THE MANAGEMENT OF LABOR AND DELIVERY

Continuous caudal analgesia is started when a patient is in labor and in distress. We advise that the procedure be not started until the patient is in actual distress. Best results are secured when the contractions are regular of at least thirty seconds duration and five minutes or less apart. Often with only slight suggestion and encouragement a patient will not need much aid until she has 3 to 4 cm dilatation. If the patient is in too severe pain the procedure can be started earlier and absolute relief given.

Under this form of analgesia the patient is continued on her normal diet and fluid intake. Thus there is no interference in the normal metabolism of either mother or child.

It is imperative that the obstetrician have a complete evaluation of the case before the analgesia is started. He should know that there is no placenta previa, molar uteri, uncontrollable hysteria or disproportion of child to pelvis. All these are extraordinary obstetric contraindications for the use of the procedure.

We prefer to keep the patient in her own hospital room until time for delivery. She is in familiar surroundings and has her reading material, radio and visitors. Since the patient is not uncomfortable she often enjoys natural sleep and is able to conserve her energy.

An enema always precedes the administration of the analgesia unless the progress of labor is too rapid. Rectal examination gives satisfactory information without producing discomfort. Rectal examination is made with facility because of the relaxation of the anal sphincter.

Because of pronounced relaxation of the soft parts of the birth canal and outlet, progress is expedited. We have found it safe to leave the mother in bed until the presenting part can be seen by spreading the vulva.

Components of Autonomic Nerve Supply to Uterus

1 Visceral efferent sympathetic (motor to upper uterine segment)	Upper thoracic and possibly lower cervical sympathetic ganglions and nerves coursing in the celiac, aortic, renal and hypogastric plexuses with possible reinforcement from nerve supply to the adnexa.
2 Visceral afferent sympathetic (sensory to the uterus)	Eleventh and twelfth thoracic and possibly the first lumbar sympathetic ganglions and nerves.
3 Visceral efferent and afferent parasympathetic (inhibitory to uterus sensory and motor to the cervix sensory to upper birth canal)	Second, third and fourth sacral nerves directly to the great cervical ganglion of Frankenhäuser.

The sympathetic components of the sacral nerves and ganglions probably also carry pain impulses from the cervix and vaginal vault and play a part in the mechanism of the dilatation of the cervix.

upper uterine segment arises from the upper thoracic sympathetic ganglions and courses in the fibers of the celiac, aortic, renal and hypogastric plexuses along the blood vessels to the uterus. These contentions have been substantiated by observations that women who have had high midthoracic traumatic sections of their spinal cords during pregnancy have continued the pregnancy and have gone into normal painless labor with spontaneous delivery. In our study of patients under continuous caudal analgesia we have found these postulates to coincide with our clinical observations. We have noticed that when the area of skin analgesia extends higher than the sixth thoracic segment the progress of labor with regard to frequency and force of the uterine contractions is delayed. So long as the area of analgesia is kept below the level of the umbilicus, the progress of labor with regard to frequency and strength of uterine contractions continues.

The nerve supply of the cervix and lower uterine segments is generally stated to course from the sacral sympathetic ganglions to the large cervical ganglions and directly through the parasympathetic fibers from the second, third and fourth sacral nerves. We believe that these fibers innervate the circular muscles of the

The danger of precipitant birth is minimized as the distressing expulsive forces called into play due to pain are absent. The mother is taken to the delivery room with the apparatus in place. The perineum is prepared with tincture of green soap and an antiseptic. The patient is draped and delivery accomplished.

It has been our policy to use prophylactic episiotomy and outlet forceps. The application of forceps is facilitated by complete relaxation. In spontaneous delivery the presenting part gradually irons out the perineum, dilates the vulva and delivers. With either operative or spontaneous delivery, care must be used to protect the mouth and nose of the child as it crosses the perineum so that there will be no aspiration. The majority of babies breathe spontaneously, since there is no drug obtunding the vital mechanism of the baby. In our experience the delivery of a breech is greatly facilitated. The premature baby has a better than average chance since it has been spared a severe dehydration period and excessive birth trauma due to resistance in the birth canal and outlet.

The third stage of labor is not prolonged and there is a noticeable decrease in blood loss. The contractile power of the uterus is not inhibited. When the patient is ready to return to her hospital bed the analgesia is discontinued.

TECHNIC FOR ADMINISTRATION

1 This method is definitely contraindicated for patients with gross deformities of the spine, particularly in the region of the sacrum, in local infection around the sacral hiatus, and for patients with a history of sensitivity to the analgesic agent.

2 The patient is placed in the modified left lateral Sims position. The sacral and coccygeal area is cleansed with soap and water and prepared with one of the antiseptic tinctures.

3 The tip of the coccyx is palpated with the middle finger of the left hand, and the thumb is used to find the U or V shaped notch indicating the sacral hiatus between the sacral cornua. This is usually about $1\frac{1}{2}$ or 2 inches from the tip of the coccyx. In cases in which there was a failure of the inferior sacral arches to fuse into the bony roof of the sacrum, this hiatus may be $2\frac{1}{2}$ to 4 inches from the inferior caudal tip. Experience with the standard single caudal injections is a desired prerequisite for success in the use of the continuous method.

4 The middle finger of the left hand then changes place with the thumb and marks the spot for raising the initial skin wheal.

5 A special apparatus, as illustrated in figure 2, has been developed for this procedure. The analgesic agent recommended by us is 1.5 per cent metycaine in isotonic solution of sodium chloride. Two Gm of the drug diluted in approximately 125 cc of a saline solution in the reservoir bottle will most nearly approach this concentration. With a few cubic centimeters of this solution skin anesthesia is obtained by raising a skin

wheel with a 25 gage and deeper infiltration to the sacrococcygeal ligament with a 2 inch 22 gage needle.

6 The special malleable stainless steel 19 gage needle is then inserted in the midline in the direction of the hiatus at about a 45 degree angle with the skin.

7 As soon as the bevel of the needle pierces the sacrococcygeal ligament its reinforced metal collar is depressed through an arc of 1 to 3 cm and the needle is thrust slowly and evenly in the midline for 1 to 2 inches within the sacral canal where its bevel should be inferior to the lowest extent of the dural sac.

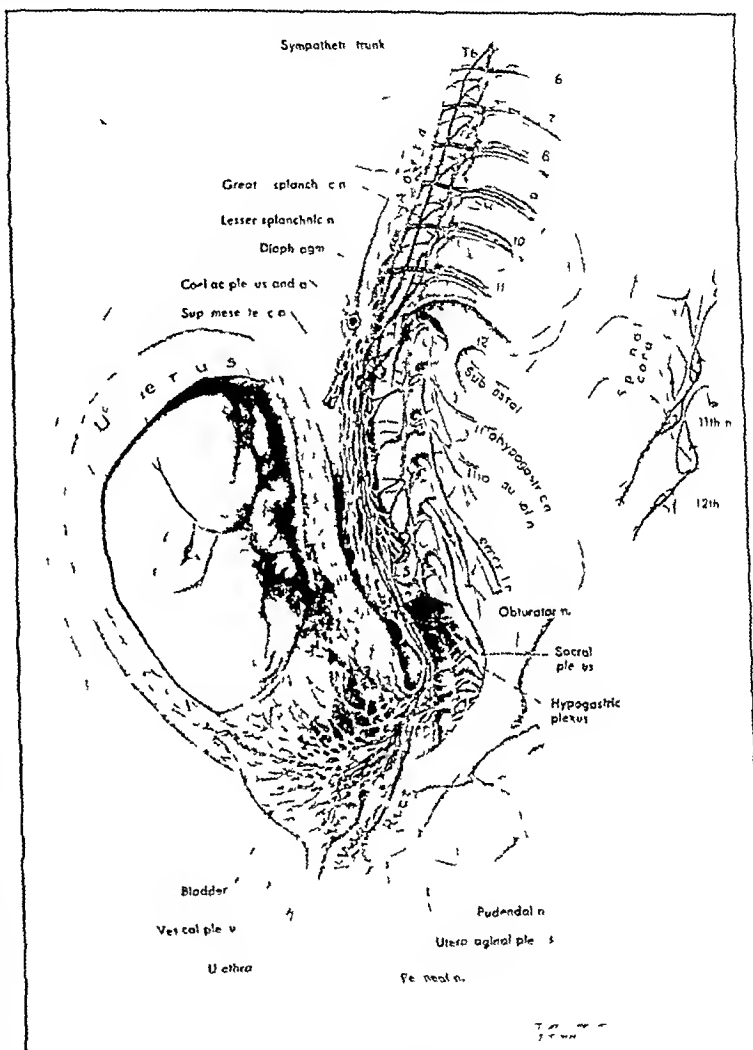

Fig. 1—The innervation of the uterus and birth canal in pregnancy. The efferent nerve fibers of the uterus constitute visceral afferent fibers and are functionally independent of the autonomic nervous system although coursing through the pelvic hypogastric and aortic plexuses before connecting with the dorsal root ganglions of the eleventh and twelfth thoracic nerves in which their nerve cells are located. The inset shows details of the connections. The sensory supply to the cervix and upper part of the vagina travels in the sacral parasympathetic nerves. It is also functionally independent of the autonomic system. The sensory and motor supply of the lower vagina, perineum and pelvic floor travels in the perineal and pudendal somatic nerves. The motor supply of the uterus is autonomic and involves both sympathetic and parasympathetic efferent components. Clinical evidence indicates that the motor fibers to the uterus leave the spinal cord at higher levels than the tenth thoracic nerve whence they pass through the aortic hypogastric and pelvic plexuses. Visceral efferent fibers believed to be motor to the circular muscle of the lower uterine segment and cervix and possibly inhibitory to the remainder of the uterus travel through the parasympathetic pelvic nerves. Clinical study verifies that (1) blocking the sacral nerve roots abolishes the pain of distention of the birth canal paralyzes the skeletal muscle of the perineum and abolishes tone in the smooth muscle of the cervix and (2) extending the block to include the eleventh thoracic root abolishes the pain of uterine contractions without impairing their force. It suggests that extending the block to the sixth thoracic nerve or higher may impair the strength of uterine contractions.

This may be ascertained by measuring on the skin with the stilet the approximate extent of the needle. The point of the needle should always be below the level of the second sacral spine.

8 The small section of tubing with special adapter is then slipped over the collar of the needle. The Luer-Lok syringe is securely attached to the adapter. A careful aspiration is performed.

(a) Should clear spinal fluid be obtained, the needle has pierced the dura and lies within the subarachnoid space. In such event the needle should be immediately withdrawn and the case ruled unsuited for caudal analgesia for fear of producing a massive spinal injection of the analgesic drug. Anatomic anomalies with such low lying dura are rare. (In our experience this has happened only twice in more than one thousand injections.) A FAILURE TO RECOGNIZE THIS SITUATION WOULD BE EXTREMELY HAZARDOUS IF NOT FATAL.

(b) The withdrawal of pure blood indicates that the needle has pierced a small blood vessel in the highly vascular peridural space. In this event the point of the needle should be moved until blood can no longer be obtained. Then the injection is continued cautiously.

Fig. 2—Apparatus and method of injection into the sacral area

9 The danger of intraspinal injection with appearance of spinal fluid previously mentioned (see 8) can be minimized if a trial dose of 8 cc. of the solution is injected and further action delayed for ten minutes to see that a low spinal anesthetic does not ensue. Without relief of pain or loss of motor power in the lower extremities in ten minutes after injection one can safely assume that the subarachnoid space was not entered.

10 After these precautions have been carried out, the hose end of the special 4 foot rubber tubing is secured over the collar of the special caudal needle. The tubing should previously have been connected to the remainder of the apparatus as illustrated in the diagram, all air having been expelled by filling the entire system with metyrcaine solution.

11 With the palm of the left hand firmly pressed over the skin area against the dorsum of the sacrum, 30 cc. of 1.5 per cent solution is slowly injected. (Epinephrine should not be used in obstetric cases, since it might produce a relaxation of the uterus.)

Indications That the Solution Is Being Injected into the Peridural Space of the Sacral Canal

(a) The patients usually experience a sense of fullness progressing to an uncomfortable sensation in one or both legs as the solution circumscribes the perineural components of the sciatic nerves. This sensation can be minimized by slower injection.

(b) There will be a progressive analgesia in the areas supplied by the coccygeal, hemorrhoidal, perineal, pudendal, iliohypogastric and iliohypogastric nerve. Analgesia should be complete in twenty minutes.

(c) There is relief of abdominal uterine cramps within five to fifteen minutes.

(d) Pronounced vasodilatation, cessation of sweating and increase in temperature of skin of feet will ensue within five to fifteen minutes after injection. This phenomenon is often noticed on one side several minutes before it occurs on the other.

Indications That the Solution Is Being Injected Outside the Sacral Canal

(a) Failure of the injection to relieve pain within thirty minutes.

(b) The appearance of an "injection tumor" superficial to the dorsum of the sacrum.

Supplementary Injections

12 The supplementary injection will depend on the rate of metabolism of the drug by the individual patient. In our experience 20 cc. of additional solution injected every thirty to forty minutes is sufficient to keep the parturient comfortable for the entire course of labor. We have continued our supplementary injections for a maximum of thirty hours and for an average of seven hours.

We consider this method of analgesia to be a specialized procedure which requires special training in order to attain uniform satisfactory results.

STATISTICAL SUMMARY

In the series of 100 cases of delivery handled by continuous caudal analgesia the percentages were as follows in the U. S. Marine Hospital, Stapleton, N. Y.: primiparas 89 per cent, multiparas 11 per cent, cephalic 98 per cent, anterior 84 per cent, posterior 14 per cent, breech 2 per cent. In this series there were only 3 per cent unsatisfactory cases in which supplementary anesthesia was necessary.

Since Jan. 1, 1942 we have either managed or supervised the labor and delivery of 489 additional cases in the clinics of nineteen medical schools and teaching hospitals. In this group there were eleven breech deliveries, one set of twins and one cesarean section. Of this series 11 per cent obtained unsatisfactory analgesia necessitating either discontinuance of the method or the addition of supplementary anesthesia. In many of these cases the technique was being practiced by residents who were learning the procedure.

In the entire series of 589 cases there were 586 live births with no maternal complications or deaths. The average length of time the analgesia was continued was six and one-half hours. The shortest was thirty-five minutes and the longest was thirty-three hours. The average metyrcaine dosage was 2.6 Gm. The maximum dosage given was 11 Gm.

In cases of toxic hypertension it was noted that after the analgesia had been in effect for about forty-five minutes the pressure reached a plateau which corresponded to their normal before they became toxic. This drop persisted until after delivery and in the cases observed did not return to the toxic peak. All the patients stated that they felt much better.

CONCLUSIONS

1 This method of analgesia in obstetrics embodies a comfortable and painless labor and delivery that is safe for mother and child

2 The analgesia is accurately developed and controlled, utilizing specially developed apparatus and technic which overcome difficulties inherent in caudal anesthetics previously to their development

3 The method can be started in any stage of labor and continued as long as necessary

4 The vital mechanisms of the child are not obtunded

5 Delivery of the child is expedited and facilitated

6 The postdelivery complications, in our experience, are reduced

7 This method involves a new analgesic technic which should be studied under those who have been trained in the method before it is employed in practice

8 Obviously, the method depends also for its success on a high degree of obstetric competence, avoiding cases in which there are contraindications, avoiding meddling or hasty obstetric intervention and observing well established criteria for observation of the progress of the delivery

CONTINUOUS CAUDAL ANESTHESIA
IN OBSTETRICS

PRELIMINARY REPORT

THOMAS G GREADY JR, M.D.

AND

H CLOSE HESSELTINE, M.D.

CHICAGO

Continuous caudal anesthesia has a place in obstetrics. There are some dangers and contraindications to this method. Cautious but repeated experiences with the method are desirable to evaluate it. These preliminary observations with some of the advantages and disadvantages are presented in the hope that others interested in this field may become aware of our experience. In this series of 20 patients there were 3 failures, 1 of these presented a typical shock reaction

TECHNIC

The same technic of administration was employed as originally described by Edwards and Hingson¹ with the precaution of waiting ten minutes after a test injection of 8 cc (90 mg) of a 1.5 per cent solution of metycaine (γ -[2-methylpiperidine]-propanol hydrochloride)². This caution was exercised to make certain that the solution did not enter the subarachnoid space. If signs of spinal anesthesia did not develop, the remainder of the initial 30 cc dose (22 cc) was injected and repeated as advised by Edwards and Hingson. One of us (T G G) administered the anesthesia in this entire group.

RESULTS

In our series of 20 cases (summarized in the table) 14, or 70 per cent, were completely successful, 3 were satisfactory but not ideal, and 3 were classified as failures. Of the 14 cases in which continuous caudal anesthesia was used during labor and delivery, 10 were completely successful and 3 others were termed satisfactory. There was 1 failure. In the 10 completely successful cases absolute relief from all labor pains was achieved. The tired, drawn, tense appearance which

was present prior to the injection disappeared. The patients became relaxed and much at ease. They were definitely pleased with the results.

In the table cases which were called satisfactory only partial relief from labor pains was obtained but the episiotomies and low forceps operations were carried out without pain. In 1 of these there was complete relief on one side with a persistence of painful sensation

Results of Continuous Caudal Anesthesia

	Total	Successful	Satisfactory	Failure
Vaginal deliveries	14	10	3	1
Postpartum abdominal sterilizations	2	2	0	0
Hysterotomy 16 weeks	1	1	0	0
Cesarean section	3	1	0	2

on the opposite side, in the other 2 it was assumed that the drug did not reach a high enough level in the epidural space to block all the uterine innervation.

The two abdominal sterilizations done following labors were completed successfully without straining and without pain when the tubes were crushed or the peritoneum manipulated. Likewise the abdominal hysterotomy on an eighteen weeks pregnancy was successful, the abdominal wall incision and the evacuation of the uterus took place with complete freedom from pain or distress.

The anesthesia was started on 3 patients for cesarean section. In 1 of these there was insufficient anesthesia of the abdominal wall for incision. Further attempts to anesthetize were not attempted. In another case, that of a toxemia of the hypertensive type, good skin anesthesia was obtained to the level of the umbilicus but the patient's blood pressure fell from 190 systolic to an indeterminate level before any operative procedure was attempted. She responded in thirty minutes after the administration of ephedrine hypodermically and oxygen inhalations. No further attempt with caudal anesthesia was made on this patient. The third section was performed successfully by means of the continuous caudal method.

COMMENT

In analyzing the 3 failures, then, we find that in 1 there was good anesthesia but the failure resulted because the patient went into vascular collapse following the injection. In the other cases the exact cause of the failure is difficult to determine, possibly a technical difficulty or possibly an anatomic variation.

It has been observed that if the solution is injected with the patient on her side (instead of in the knee chest position) the most dependent side is the first to become anesthetized and that the level of anesthesia extends higher on the dependent side. In some cases it seemed possible to get a higher level of anesthesia by injecting with the patient in the Trendelenburg position. There seems to be a direct proportion between the amount of drug given in a single injection and the level of anesthesia on the abdominal wall and also between the force of injection and the level of anesthesia.

The longest continuous period over which the drug was administered was eight hours, the procedure usually being started when the cervical dilatation was 5 cm or more. Practically all patients showed a drop in blood pressure from 10 to 30 points or more, the greater falls occurring in patients with some hypertension, 2 had a secondary rise in pressure to above the previous maximum when the anesthesia wore off.

A few minor side reactions besides blood pressure changes were encountered. Two patients complained of severe pains in the back and legs after the drug

² Eli Lilly and Company furnished the metycaine used in this study.

wore off, 1 requiring morphine for relief. Neither had any sequela during the remainder of the puerperium. One patient with whom the anesthesia was successful complained of severe throbbing headache during the injection. This lasted for about three minutes and recurred with each subsequent injection, lasting the same length of time. Another patient complained of severe burning pain in the lower extremities beginning a few seconds after each injection and lasting about one minute. This was obviated by giving subsequent injections while anesthesia was still complete.

The method should be safe provided the anesthetic agent is injected extradurally. The epidural space is composed of loose, vascular, areolar tissue and in some places the space is much narrower than in others. It continues all the way to the foramen magnum, theoretically it would be possible to block the phrenic nerve, which receives its innervation from the second to the fifth cervical. However, this possibility is remote because of the pronounced discrepancy between motor and sensory loss. Motor loss is in most cases only partial even in the lower extremities. Therefore the danger of respiratory paralysis would seem to be less likely than in spinal anesthesia.

ADVANTAGES AND INDICATIONS

The continuous caudal method of anesthesia possesses advantages:

- 1 It is a useful form of nerve block anesthesia when a general anesthetic is contraindicated, as in pulmonary tuberculosis or upper respiratory infections.

- 2 The uterus appears not to relax and appears to maintain its normal motility and mechanism in contrast to its behavior under deep inhalation anesthesia.

- 3 Narcotics and sedatives are eliminated during the course of labor and delivery.

- 4 The procedure is a relatively simple one and seems safe for those skilled in this procedure.

- 5 At laparotomy (cesarean section) the peritoneum is not sensitive as it is when done under local anesthesia.

- 6 Patients in labor are calm, quiet, relaxed and rational.

- 7 It makes use of the principle of giving repeated amounts of a drug over a long period of time.

DISADVANTAGES AND CONTRAINDICATIONS

Some of the conditions which present themselves and which might be presumed to be disadvantageous and dangerous are:

- 1 The greatest danger would seem to be that of injecting this amount of drug into the subarachnoid space. The two safeguards are aspiration before injection and the injection of 8 cc (90 mg) for test of spinal anesthesia.

- 2 There is a loss of the subjective pain element as an aid to following the progress of labor.

- 3 When compared to the administration of a hypodermic or to oral routes of administration for analgesia during labor it can be seen that it is not a time saving procedure since a skilled person must insert the needle and inject the medication at intervals of thirty minutes or longer. This requires the attention of a physician.

- 4 It either prolongs the second stage or increases the incidence of operative delivery, since the patient has absolutely no urge to bear down.

- 5 While this type of anesthesia has the advantage of providing a contracting uterus for normal labor and third stage it is not the procedure of choice when a difficult forceps rotation or version is necessary, since here almost complete uterine relaxation is imperative.

- 6 Since 1 toxemic patient had a vasomotor or shock reaction, other toxemic or severe hypertensive patients have not been tested with this method.

- 7 It is assumed that the successful administration will increase from 70 per cent in the series of 20 patients to a distinctly more favorable rate as experience and judgment increase. It seems that an occasional failure is unavoidable because of the peculiar configuration of the sacrum.

- 8 The method does not give abdominal wall relaxation as compared to deep inhalation anesthetics.

- 9 That spinal anesthesia is contraindicated in cardiac patients with myocardial damage is a general belief, and the same may apply for continued caudal anesthesia.

- 10 At this time the procedure seems to be one exclusively for hospital usage because of the danger of complications.

It is our belief that in carefully supervised and selected cases continuous caudal anesthesia is a valuable addition to the field of obstetric analgesia and anesthesia and our work with it is continuing.

MODERN TREATMENT OF PNEUMOCOCCIC PNEUMONIA

HARRISON F. FLIPPIN, M.D.

LEON SCHWARTZ, M.D.

AND

ALBERT H. DOMM, M.D.

PHILADELPHIA

Within the past five years numerous clinical reports have established that sulfonamide therapy, properly conducted, is an effective form of treatment for pneumococcal pneumonia. It is appropriate at this time, therefore, to evaluate the comparative merits of the sulfonamide compounds which have been used in the treatment of pneumococcal pneumonia as well as to consider some of the more important problems concerned with their rational use. This report is based on experience with 1,635 cases of pneumococcal pneumonia of adults treated with sulfapyridine, sulfathiazole or sulfadiazine in the medical wards¹ of the Philadelphia General Hospital between Aug. 15, 1938 and April 1, 1942.

For this study we have included all patients with a diagnosis of pneumococcal pneumonia who received sulfapyridine, sulfathiazole or sulfadiazine regardless of the amount of drug administered. In general the three therapeutic groups were comparable as to distribution of sex, race, age, pneumococcus type, antecedent disease and the day of illness on which chemotherapy was started. However, the three drugs were used for the most part during different pneumonia seasons or in different months of the same season (chart 1) and one cannot say definitely whether the disease itself was of the same severity throughout the period of this study. If the severity of the disease is based on the relative incidence of bacteremic cases it would appear (chart 1)

Dr. Domm is David Riesman Fellow in Medicine. This investigation was aided by a grant from the American Philosophical Society.

Read before the Section on Practice of Medicine at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

Dr. William G. Turnbull, Superintendent and Miss Loretta Johnson, Directress of Nurses, showed constant interest and gave helpful suggestions in the conduct of this study.

From the Committee for the Study of Pneumonia, the Philadelphia General Hospital. Other members of this committee include Drs. J. H. Clark, J. G. Reinhold and S. B. Rose.

¹ Clinical facilities were given us for this study by the chiefs of the medical services.

that pneumococcal pneumonia was more severe during the last two years, also there was a definite decrease in the total number of cases within this same period (chart 1). It is possible that the relative increase in bacteremic cases and the appreciable decline in the number of pneumonia admissions were the result of an increasing trend toward home care of patients, and, for the most part, only the more severe cases were hospitalized. However, of equal importance were certain refinements in laboratory methods, particularly the employment of an antisulfonamide, para-aminobenzoic acid,² in culture mediums.

The use of para-aminobenzoic acid in blood cultures was commenced in January 1941, and it was about this time that the incidence of bacteremic cases began to rise. It is likely that a number of blood stream infections were not detected in our earlier studies, as in some of our cases samples of blood for culture were not obtained until after one, or sometimes two, doses of the drug had been given, and in addition a number of patients had received some form of sulfonamide therapy before admission to the hospital. Therefore the severity of these pneumonia cases cannot be judged on the basis of bacteremia alone, although we are of the opinion that there was a relative increase in the incidence of severe pneumonias observed in this hospital during the last two years of this study. As shown in table 1, the gross mortality for this entire series of cases was 10.6 per cent. When this fatality rate is compared to that of 40.1 per cent obtained in 1,904 cases observed in this hospital during the five years prior to the introduction of these chemotherapeutic agents, the effectiveness of this form of therapy is obvious.

COMPARATIVE THERAPEUTIC EFFECTIVENESS

The effectiveness of a chemotherapeutic agent for the treatment of pneumococcal pneumonia may be evaluated from the study of (1) the effect of the agent on mortality, on incidence of complications, and on the course of the disease, (2) the toxic effects on the patient and (3) the pharmacologic behavior of the drug in man.

MORTALITY RATES, INCIDENCE OF COMPLICATIONS AND INFLUENCE OF TREATMENT ON THE COURSE OF THE DISEASE

Sulfapyridine, sulfathiazole and sulfadiazine were comparable in effectiveness as judged by the mortality rates (table 1) of 9.7, 12.1 and 10.3 per cent for the three therapeutic groups. Positive blood cultures for pneumococci were obtained in 10.9, 15.0 and 22.2 per cent of patients receiving sulfapyridine, sulfathiazole and sulfadiazine with mortality rates of 32.5, 43.3 and 25.5 per cent respectively. However, as mentioned before, one cannot be certain as to the significance of bacteremia as an index of the relative severity of the cases in each therapeutic group. The incidence of complications was low and comparable in the three drug treated groups (table 2). The most striking clinical observation with the three drugs was the frequency with which the initiation of drug therapy was followed within twenty-four to forty-eight hours by a critical drop in temperature. The action of sulfapyridine³

and sulfadiazine⁴ in lowering the temperature was more rapid than that of sulfathiazole although the average duration of treatment and the average stay in the hospital was practically the same for all three drug treated groups.

TOXIC EFFECTS

In our experience (table 3) with these drugs in pneumococcal pneumonia the incidence and severity of toxic reactions following sulfadiazine therapy were less than those observed in patients receiving sulfapyridine or sulfathiazole. This difference in toxicity was principally the relatively lower incidence of untoward gastrointestinal and renal manifestations associated with sulfadiazine treatment.

PHARMACOLOGIC BEHAVIOR IN MAN

In previous papers⁵ we have presented data on the absorption, acetylation and excretion of sulfapyridine, sulfathiazole and sulfadiazine in pneumococcal pneumonia patients. Sulfadiazine given orally yields higher concentrations of the free drug in the blood and smaller proportions of acetylated drug in the blood and urine

Chart 1.—Number of cases treated, incidence of bacteremia and mortality percentage in each year of this study. The three drugs were employed for the most part over the designated periods.

than do sulfapyridine or sulfathiazole. Furthermore, acetylsulfadiazine is more soluble in urine than is acetylsulfapyridine or acetylsulfathiazole. These differences in the relative degree of acetylation and solubility of the acetyl derivatives appear to have an influence on the incidence and severity of urinary tract complications following the use of these drugs (table 3). When these compounds are administered intravenously, higher concentrations of the drug are maintained for longer periods with sodium sulfadiazine than with sodium sulfapyridine or sodium sulfathiazole. This is of decided value in the control of infection in certain types of cases.⁶

On the basis of the foregoing data it would appear that the drug of choice for the treatment of pneumococcal pneumonia at the present time is sulfadiazine.

ROUTINE MANAGEMENT OF PNEUMOCOCCIC
PNEUMONIA

Early Treatment—With the exception of the age of the patient (chart 2) and certain others factors⁷ beyond the physician's control, the length of time that elapses between the onset of the infection and the beginning of specific treatment is the most important single controllable factor in the prognosis of pneumococcic pneumonia. As indicated in chart 3, there was a definite increase both in the mortality rate and in the incidence of complications in those cases in which chemotherapy was started after the first forty-eight hours of the illness. Hence the best results with these drugs are obtained when they are administered early in the infection, while the number of bacteria is still limited and the extent of tissue involvement is at a minimum. Certainly, sulfadiazine treatment should not be withheld just because

response of patients receiving sulfadiazine are still in the experimental stage and are as yet of doubtful clinical significance.⁹ Thus it is difficult to outline a course of sulfadiazine therapy which will theoretically be effective, but it seems reasonable, for practical purposes, to administer the drug in a manner which experience indicates will probably be adequate for the treatment of pneumococcic pneumonia of adults.

In general, the oral route has proved to be the most practical method of administering sulfadiazine, although in certain instances its parenteral use is indicated. As a rule, sulfadiazine is readily absorbed from the intestinal tract into the blood stream, reaching levels of 4 to 6 mg of free drug per hundred cubic centimeters within four to six hours after the oral administration of a single (3 to 4 Gm) dose. After the fourth to the sixth hour the amount of drug in the blood begins to

the case is considered mild. Likewise the use of drug should not be delayed in a suspected case of pneumonia until signs of consolidation have appeared. Obviously, this does not mean that every person suffering with a mild infection of the upper respiratory tract is to be regarded as a pneumonia suspect.

Adequate Chemotherapy—Theoretically, in order to obtain maximum therapeutic results with sulfadiazine in pneumococcic pneumonia it is necessary to administer the drug in such a manner as to obtain an effective concentration of free drug in the blood as soon as possible and to maintain an adequate level until the patient has developed sufficient immunity against the infection to prevent a relapse. However we have been unable to establish an optimal blood concentration for sulfadiazine in the treatment of pneumococcic pneumonia,⁸ and, furthermore, methods for determining the immunity

diminish and if the blood concentration of the drug is to be maintained or increased it is necessary to administer additional drug in smaller amounts every four to six hours until the total dosage has been given. Since varying blood levels of the drug result in diminished therapeutic effectiveness, it is important to adhere to this schedule of dosage. As already mentioned we have been unable to determine any definite correlation between the effectiveness of sulfadiazine and the concentration of free drug in the blood although it appears that if a free blood level of 5 to 10 mg per hundred cubic centimeters is maintained, satisfactory results may be expected. In this connection it should be remembered that such factors as drug absorption and kidney function tend to influence the amount of drug found in the blood, since the drug concentration reached in the blood is dependent both on the rate of entry into and the rate of exit from, the blood stream. On the basis of these considerations and after employing several schemes of

dosage, we have adopted the following dose schedule for the treatment of pneumococcal pneumonia of adults with sulfadiazine

An initial 3 Gm dose of sulfadiazine is given orally and followed by 1 Gm every six hours thereafter, until the temperature has remained normal for forty-eight

hours and the patient shows clinical evidence of improvement. It is possible in most cases to adhere to this six hour dose schedule, but occasionally when a higher blood level of drug is desired, the 1 Gm dose is given at four hour intervals until the desired drug concentration in the blood is obtained. In order to give sulfadiazine parenterally it is necessary to employ its sodium salt. Best results with sodium sulfadiazine parenterally are obtained with its intravenous use. For intravenous therapy a 5 per cent solution of sodium sulfadiazine in sterile distilled water is employed. Obviously, when the drug is administered by vein, higher blood levels of free sulfadiazine (10 to 18 mg per hundred cubic centimeters) are obtained more rapidly (within fifteen minutes) than when equal amounts (3 to 4 Gm) are given by mouth. As a rule, this form of therapy is resorted to for those patients in whom a more rapid elevation of the blood level of drug is desired or when

oral medication is impracticable. Patients who are unable to take sulfadiazine by mouth are given an initial 3 to 4 Gm dose of sodium sulfadiazine intravenously, followed by 2 Gm every twelve hours thereafter until the total dose has been given. Frequently it is well to give seriously ill patients a large initial dose of drug (3 to 4 Gm) by vein and at the same time start giving 1 Gm doses every four to six hours by mouth. In general, the total dosage of sulfadiazine is 20 to 30 Gm depending on such factors as the day of disease when

treatment was started, the presence of bacteremia, spread of the infection, complicating diseases, kidney function and drug toxicity. It is to be remembered that once drug treatment has been started, it is to be continued, unless signs of severe toxicity develop until convalescence is established. Not infrequently a fall in temperature proves deceptive and a spread or recurrence in the infection occurs if chemotherapy is stopped too early. Although it is not generally necessary, a safe procedure to follow, when in doubt, is to reduce the dose of drug gradually over a period of days and watch the patient carefully for evidence of recurrent infection.

Fluid Balance—Sulfadiazine regardless of its route of administration is excreted mostly in the urine, and its elimination is reduced in the presence of kidney damage. Therefore, with a decrease in kidney function an increase in drug concentration in the blood occurs and, should the volume of urine become low, the possibility of stone formation in the urinary tract by pre-

Chart 2—Influence of age on mortality in 1 635 cases

cipitation of crystals of acetylsulfadiazine is greatly increased. However, the excretion of sulfadiazine, both the free and acetylated forms, is definitely increased by an increased rate of flow of urine. Hence it is of importance, in order to facilitate the excretion of the drug by the kidneys, to maintain a urinary output of at least 1,200 cc in each twenty-four hour period. This is best obtained by forcing fluids, either by mouth or, if necessary, parenterally.

Use of Alkalis—The renal complications following sulfadiazine therapy are due in part, if not entirely, to the presence in the urinary tract of crystals composed of the drug, especially the acetyl portion. Since crystalluria from sulfadiazine appears to be less frequent in an alkaline urine,¹⁰ it is advisable to administer alkalis to patients receiving the drug. It has been our practice to give equal amounts of sodium bicarbonate or sodium citrate to all sulfadiazine treated pneumonia patients.

10 Schwartz Leon, Flippin H F, Reinhold J G and Domm A H. The Effect of Alkali on Crystalluria from Sulfathiazole and Sulfadiazine. *J A M A* 117: 514 (Aug 16) 1941.

who showed evidence of renal impairment, and it seems practical to administer an alkali routinely to all patients receiving sulfadiazine therapy

Supportive Measures—Regardless of the therapeutic value of sulfadiazine in pneumococcic pneumonia, it is not to be used to the exclusion or neglect of established supportive measures. The pneumonia patient requires competent nursing care, complete mental and physical rest, sufficient fresh air easily digested food and adequate bowel elimination. The intelligent use of morphine still constitutes one of our principal aids in the control of certain disturbing features of this disease, such as apprehension, restlessness and pain. Fortunately the severity of abdominal distention is less pronounced in pneumonia patients receiving chemotherapy than was formerly observed, although occasional patients will require enemas, rectal tubes, local heat to the abdomen and the use of drugs like solution of posterior pituitary. In general it is best to avoid the employment of cathartics. Digitalis should be administered when indicated, but not as a routine procedure. We know of no medication or food which cannot be given to pneumonia patients treated with sulfadiazine

Chart 3—Mortality and incidence of complications in relation to the length of time that elapsed between the onset of the disease and the beginning of treatment in 1635 cases

Control of Drug Toxicity—Although the incidence and severity of toxic reactions following the use of sulfadiazine in pneumococcic pneumonia are not as severe as those encountered with sulfapyridine or sulfathiazole therapy, it must be remembered that the drug is not entirely harmless to the host.

The vomiting that sometimes follows treatment with sulfadiazine is rarely so severe as to necessitate stopping the drug, but if it becomes so it is advisable to check the fluid and salt balance. Cutaneous and episcleral reactions may occur at any time after the drug is administered but usually after the third day of treatment. Usually it is best to stop the drug, although in certain instances, when necessary, it can be continued with caution. Acute hemolytic anemia has not been observed by us but others¹¹ have reported the development of this condition. In such cases the drug should be discontinued and blood transfusions employed. Toxic reactions involving the white blood cells are essentially negligible in the treatment of uncomplicated cases of pneumonia.¹² Occasionally a patient will develop leuko-

pemia, but unless the drug is given for ten days or longer this condition should not cause undue apprehension. Obviously a progressive lowering of the white blood count with a decrease in polymorphonuclear cells below 40 per cent is to be respected, although the severity of the illness not infrequently prevents the stopping of the drug unless type specific serum is available.

Fever due to sulfadiazine may occur at any time but usually after the fourth day. At times it is difficult to determine whether the temperature rise represents a drug reaction or a recrudescence of the infection. The fever of the original infection is usually normal by the third day of treatment, except when complications develop, if the patient is clinically improved, a secondary rise in temperature may usually be attributed to the drug. In such cases, if chemotherapy is stopped and fluids are forced, the temperature will drop within twenty-four to thirty-six hours. Whenever possible, it is best to discontinue chemotherapy in the presence of drug fever, as not infrequently this condition is followed by more serious toxic reactions. Psychoses due to sulfadiazine are difficult to evaluate in seriously ill pneumonia patients, but they do occur and, unless the infection is under control, there is no necessity to withdraw the drug.

Toxic reactions involving the urinary tract may occur with sulfadiazine at any time but are most commonly seen after the fifth day of treatment. As mentioned before, the renal complications from sulfadiazine are due in part, if not entirely, to the presence in the urinary tract of crystals composed of the drug. However the presence of crystalluria alone does not indicate renal involvement unless it is associated with progressing oliguria, hematuria, azotemia or loin pain. In this study, approximately one fourth of the sulfadiazine treated patients showed crystals presumably of the drug, in the urine. Microscopic hematuria was observed in 4.4 per cent of these patients, which is only slightly above the reported incidence of hematuria in cases of untreated pneumonia.¹³ Unless a considerable number of red blood cells are detected or other evidence of renal damage is apparent cautious treatment may be continued, but it should be remembered that hematuria is often a precursor of severe renal insufficiency. Obviously the appearance of gross hematuria is an indication for stopping the drug. Although no anuria, renal calculi or loin pain was seen in this group of pneumonia cases treated with sulfadiazine, we have encountered these complications. In practically every instance in which a severe renal reaction to sulfadiazine has been observed, alkalis or adequate quantities of fluids had not been given and sulfadiazine had been administered over a period of four or more days. It is our impression that the relatively low incidence of renal complications in this series of sulfadiazine treated cases may be related to the emphasis that was constantly placed on adequate fluid intake during drug therapy and the administration of alkalis. Should any of the kidney complications mentioned be encountered during sulfadiazine therapy, the treatment consists in prompt cessation of the drug, alkalization of the urine forcing of fluids, administration of hypertonic dextrose solution to promote diuresis and urethral catheterization, if necessary. The administration of mercurial compounds as diuretics or the use of magnesium sulfate as a cathartic is contraindicated in such cases.

CONTRAINDICATIONS TO SULFADIAZINE THERAPY

Theoretically, the only possible contraindication to the use of sulfadiazine in pneumococcal pneumonia is a history of a previous sensitivity to one of the sulfonamide compounds. However, in our experience there have been a number of patients who have developed toxic reactions to one of these drugs and not to another member of this group of compounds, although this would not necessarily indicate that the patient would not have had a toxic reaction if the original drug was used again. If a history of previous drug toxicity was obtained and the patient required immediate specific treatment it has been our practice to use chemotherapy at once and follow the patient very closely for possible drug toxicity, rather than delay specific treatment until the administration of serum was made possible. In such cases we selected the drug least likely to cause the same type of toxic reaction (table 3). It is too early to say whether the widespread use of the sulfonamides will result in an increasing number of patients developing sensitivity to these drugs, but in view of the frequency with which pneumococcal pneumonia recurs, this problem merits further consideration. In a series of 24 adults having recurrent pneumococcal pneumonia treated with sulfapyridine, sulfathiazole or sulfadiazine on two or more occasions there was no evidence to suggest that the repeated use of these compounds had influenced the incidence or severity of drug toxicity.¹⁴ The presence of jaundice, acute nephritis, anemia, leukopenia or neutropenia per se in a pneumonia patient does not contraindicate drug therapy, as these conditions will usually disappear as the infection is brought under control by adequate sulfadiazine treatment. Obviously, if such conditions are present, necessary measures should be taken to detect their further development.

MANAGEMENT OF COMPLICATIONS

The presence of pus in a lesion prevents the sulfonamides from acting on bacteria with the same maximum effect which they exhibit in diffuse, nonsuppurating infections. Sulfadiazine, therefore, is not to be employed as a substitute for surgical procedures in complications from pneumonia, such as empyema or abscesses, although the drug may be used in the hope of preventing a spread of the infection. Usually, in cases of massive pleural effusion, chemotherapy and thoracentesis will prove sufficient, but, if the effusion is thick and purulent surgical intervention is indicated. Not only is the early diagnosis of pus-containing lesions in cases of pneumonia of great importance as an aid in treatment but also the incidence of severe drug reactions is greater in patients receiving chemotherapy over long periods of time.

TYPE SPECIFIC SERUM

For the most part the role of type specific serum in the treatment of pneumococcal pneumonia remains a controversial subject. Certainly there is no clinical basis for its routine use,¹⁵ although there are certain pneumonia cases which are benefited by the administration of serum in combination with chemotherapy. For the most part we have limited the use of serum alone to cases in which severe drug reactions prevented the further use of chemotherapy, and of serum plus drug

in cases that failed to respond satisfactorily to the drug within twenty-four to forty-eight hours. On this basis type specific serum was employed in 124 (76 per cent) of our cases (table 4) with a mortality of 37.9 per cent. Whether the successfully treated patients in this subgroup would not have recovered without the additional use of serum, we cannot say. There were however a number of seriously ill patients who showed a prompt clinical response after serotherapy. Not infrequently serum was employed in cases with serious antecedent and/or complicating diseases with little or no expectation of its being effective. Unfortunately concentrated efforts were not made to determine which of the cases in the combined therapy group represented drug fast infections or failures in immunity response. Obviously these two factors constitute the basis for the rational use of serum in those cases failing to respond to chemotherapy. No doubt, with the development of more accurate methods to evaluate these factors, the employment of type specific serum will play a more definite role. At the present time it seems reasonable to use serum for patients unable to tolerate the drug and patients failing to respond to chemotherapy. When administering serum, the usual preliminary sensitivity tests, conjunctival and intradermal, must always be

TABLE 4—Combined Therapy Cases

performed. If these prove negative after twenty minutes, further intravenous testing with undiluted serum (1 cc) is carried out. If after seventy minutes no untoward reaction has occurred the patient is given an initial dose of 100,000 units of undiluted serum intravenously, followed by further injections when necessary. In general, if serum is beneficial the patient will respond to 300,000 units or less.

LABORATORY PROCEDURES

The employment of certain laboratory procedures is of great importance in the diagnosis and treatment of pneumococcal pneumonia. In every case there should be adequate bacteriologic studies to determine the type of pneumococcus responsible for the infection. It is true that in most cases of pneumonia this information is of no therapeutic value, but in instances in which type specific serum is indicated, a knowledge of the pneumococcus type is indispensable. Blood cultures should be obtained as soon as possible. As already mentioned, if an antisulfonamide substance, para-aminobenzoic acid (5 mg per hundred cubic centimeters of medium) is added to the culture material the inhibitory action of the sulfonamide will be neutralized. This procedure should be adhered to whenever the patient has received even small doses of any sulfonamide. The sputum should be studied to determine the pneumococcus type, but in cases in which there has been some delay in

14 Schwartz Leon, Flippin H F and Clark J H. Recurrent Pneumococcal Pneumonia Treated with Sulfonamides. J Lab & Clin Med to be published

15 Plummer Norman, Liebmann James, Solomon Saul, Kammerer W H, Kallstein Mennasch and Ensworth H K. Chemotherapy Versus Combined Chemotherapy and Serum. J A M A 116: 2366 (May 24) 1941

typing, and the blood culture is positive, this examination is not necessary

A blood count, including hemoglobin determination, leukocyte count and a differential enumeration of the white blood cells should be done, preferably before the institution of drug therapy. It is best to check these blood constituents every two or three days, especially in cases in which the drug is required for longer than ten days. There is no absolute relationship between the number of leukocytes and the severity of the infection. In general a high initial white count which diminishes rather rapidly after forty-eight hours of treatment with the drug is of good prognostic import, while a persistent or progressively high count often indicates a spread in the infection or a complication. Patients with low initial white counts are often seriously ill, but if they respond to treatment the count will usually increase within forty-eight hours. The failure of a low white cell count to rise is generally a poor prognostic sign.

Because of the potential dangers of sulfadiazine to the urinary tract, it is important to watch every patient closely for evidence of renal damage. The total amount of urine voided in each twenty-four hour period should be recorded, as well as gross and microscopic urine studies daily to detect any evidence of kidney irritation. Blood urea nitrogen or nonprotein nitrogen determinations should also be performed in cases in which there are diminishing urinary outputs and serum chlorides should be determined in cases in which appreciable quantities of fluid and electrolyte are lost. In most instances it is not necessary to determine the blood concentration of sulfadiazine. However, in cases failing to respond satisfactorily to the drug or with diminishing urinary outputs it is practical to ascertain the amount of drug in the circulating blood.

SUMMARY AND CONCLUSIONS

Within the period of this study, Aug 15 1938 to April 1, 1942, 1,635 adults with pneumococcal pneumonia were treated with sulfapyridine, sulfathiazole or sulfadiazine with an averaged mortality of 10.6 per cent. This figure is to be compared to that of 40.1 per cent mortality obtained in 1,904 cases of this disease observed at the Philadelphia General Hospital during the five years prior to the introduction of these drugs. From the data presented in this report it appears that sulfadiazine is the drug of choice at the present time for the treatment of pneumococcal pneumonia. To obtain maximum therapeutic results with sulfadiazine in pneumonia, certain principles must be recognized and followed. Regardless of the effectiveness of sulfadiazine in pneumococcal pneumonia, it is not to be employed to the exclusion or neglect of other established therapeutic measures. The following plan of sulfadiazine treatment of pneumococcal pneumonia is suggested:

- 1 Early treatment
- 2 Adequate chemotherapy
 - (a) Large initial dose
 - (b) Smaller doses at regular intervals
 - (c) Continuation of drug until convalescence is established
- 3 Maintenance of adequate urinary output
- 4 Routine use of alkalis
- 5 Prompt recognition of drug toxicity
- 6 Determination of specific pneumococcus type
- 7 Employment of other therapeutic measures as necessary
 - (a) General supportive treatment
 - (b) Type specific serum
 - (c) Surgical procedures

ABSTRACT OF DISCUSSION

DR ADOLPH S. RUMREICH, Chicago. Dr Flippin and his associates have given a comprehensive presentation of up to date treatment of pneumococcal pneumonia. Their work demonstrates the encouraging results that can be achieved on a large scale by the proper use of present day diagnostic facilities and therapeutic armamentarium. The great reduction in mortality from pneumonia since the introduction of specific chemotherapy seems to have led to a complacent assumption in some responsible quarters that the problem has been all but liquidated and that it need no longer be a cause for concern on the part of public health authorities. However, as Dr Bortz has pointed out, there still occur thousands of preventable deaths from this cause. Dr Flippin has stated that the length of time that elapses between the onset of the infection and the beginning of specific treatment is the most important single controllable factor in the prognosis of pneumococcal pneumonia. Control of this element alone is worthy of the best joint effort of medical organizations and public health departments, in the promotion of early medical attention, prompt and accurate diagnosis and prompt and adequate modern treatment. The good results of statewide cooperative programs are susceptible of proof. Opinions differ as to the desirability of universal treatment of respiratory tract infections with sulfonamide compounds, and practices differ accordingly. None of these drugs are panaceas, nor are they innocuous. That they are specific in pneumococcal and useful in certain other pneumonias does not warrant their indiscriminate use as they are not only valueless but may be definitely harmful in some of the atypical pneumonias. We cannot yet safely dispense with accurate diagnosis and forgo utilization of clinical laboratory and other adjunct facilities. The increasing trend toward home care of patients, reflected favorably in case fatality statistics, not only redounds to the welfare of the patient but tends to conserve community resources. The current trend thus seems to be all to the good, provided there is sustained endeavor for maintenance of proper safeguards in order that the maximum benefit of our remarkable new tools and weapons may be achieved.

DR WORTH B. DANFIS, Washington, D. C. The section might be interested in our experience with pneumonia at a large army cantonment hospital. The Station Hospital at Fort Bragg, North Carolina has 3,000 beds and serves a large military population. During the year 1941 there were 488 patients with pneumonia with five deaths, a mortality of approximately 1 per cent. Four of these patients died with pneumonia occurring secondary to other illness, 1 died of atypical pneumonia and none of lobar pneumonia. During the first five months of 1942 there have been 552 patients admitted with pneumonia, 384 were diagnosed as having lobar pneumonia and 164 as having atypical pneumonia. There has been one death, and this occurred in a civilian literally deposited on our door step in a moribund state on the tenth day of his illness. The mortality rate for this five months period is approximately 0.2 per cent. During 1941 and the first five months of 1942 there have been 1,040 patients admitted with pneumonia of various types and 6 have died. The mortality therefore, has been 0.6 per cent. You will notice that during the last five months the total number of patients with pneumonia has exceeded the number for the entire year 1941, though there has been little change in the post strength. This is attributable to the increase in so called atypical pneumonia, which has recently become prevalent or better recognized throughout the country. The communicability of this disease has now been clearly shown and accounts for the high incidence among troops and other closely associated groups of young persons. As you may know, two of the earlier descriptions of this disease were contributed by army physicians, Bowen in Hawaii in 1935 and Allen at Fort Sam Houston, Texas, in 1936. Our remarkably low mortality is probably due to five factors: 1 The material with which we deal, namely, a group of picked, vigorous young soldiers. 2 Admission to the hospital very early in the illness, with immediate institution of therapy. 3 The curative properties of the sulfonamides in pneumococcal pneumonia. 4 Segregation of patients with pneumonia in wards administered by medical officers, nurses and soldier attendants who have become expert in the handling of this disease. 5 The mild character

of the atypical pneumonias we have encountered Sulfathiazole was used almost exclusively until February of this year but is being gradually replaced by sulfadiazine Various toxic effects have occurred, but rarely have serious complications arisen It would appear that the modern treatment of pneumonia in a large cantonment hospital caring for troops not actually engaged in combat has maintained the mortality of this disease at 0.5 per cent

DR HARRISON F FLIPPIN Philadelphia As pointed out by Dr Daniels and Dr Rumreich, the problem of atypical, or so called virus, pneumonias is becoming more apparent There is little or no reason to believe that sulfonamide therapy is effective in this type of pneumonia However it is often difficult to determine whether a patient is suffering with this particular disease, and for this reason it has been our practice to administer sulfadiazine to all pneumonia patients for at least seventy-two hours, and if within that time no clinical improvement has been noted the drug is stopped The most important aspect of sulfadiazine therapy at present is that of urinary tract complications Again we wish to emphasize the importance of maintaining an adequate urinary output and the routine use of alkalis Although sulfadiazine is not ideal it is the best drug now available for the treatment of pneumococcal pneumonia, and if it is used with regard for its toxic possibilities, and if the patients for whom it is used are thoroughly studied and carefully followed it is a therapeutic agent with a satisfactory margin of safety

SESAME OIL TUMORS

ADOLPH H. CONRAD, M.D.
ADOLPH H. CONRAD JR., M.D.
AND
RICHARD S. WEISS, M.D.
ST. LOUIS

In 1920 Mook and Wander¹ described the occurrence of painful, tender, slowly growing tumors in 6 patients who had been previously subjected to serious operations and had received camphor in oil injections as a stimulant Several similar cases have since come under our care and we have seen others in clinical meetings in various cities throughout the country In all of the cases seen the camphor oil injections had been made many years previous to our observation Pharmaceutical houses, since the publication of Mook and Wander's report have generally discontinued the sale of camphor

Fig. 1—Gross tumors (about half natural size) removed from arm. The globular dark areas are oil filled cysts.

and other drugs dissolved in liquid petrolatum We have been watching for tumors due to the injection of other oils because we knew that Burrows and Johns-

ton² were able to produce oil tumors in rats by the subcutaneous injection of corn oil The tumors which they produced did not show as much cellular reaction as the camphor oil tumors, probably because of the lack of the irritant action of camphor It should also be noted that a case of multiple tumors in the buttock was reported by Irwin Sutton³ following the injection

Fig. 2—Cyst wall and infiltrate surrounding cyst (magnification about 95 diameters)

of mercuric salicylate in linseed oil Weidman and Jeffries⁴ concluded that olive oil and cottonseed oil were innocuous when injected subcutaneously but admitted that their position was somewhat insecure on this point Burrows and Jorstad⁵ found that oil tumors which had remained small and quiescent for years became active almost at once when the patient was placed on a salt poor and vitamin poor diet Jorstad and Glenn⁶ intimated that the vitamin concerned is vitamin A It is attractive of course, to theorize that oil tumors occur in patients who habitually are on a diet low in vitamin A but no definitive proof exists as yet that such is the case

A patient came under our observation who had tumors clinically identical with those reported by Mook and Wander The oil injected was sesame oil containing estrogenic substance

REPORT OF CASE

Mrs. M. V., a white woman aged 35, admitted to the skin clinic of the Barnard Free Skin and Cancer Hospital on March 12, 1940, complained of painful lumps in both arms which she stated had been present since 1935.

Studies, Observations and Reports from the Dermatological Departments of the Barnard Free Skin and Cancer Hospital and the Washington University School of Medicine, service of Dr. M. F. Engman, M.D.

¹ Mook, William H. and Wander, William G. Camphor Oil Tumors. *Arch. Dermat. & Syph.* 1: 304-318 (March) 1920.

The relevant items in her history were as follows. In 1929 she had had a unilateral salpingo oophorectomy done. In 1934 a second operation was done, at which time the uterus and the remaining fallopian tube and ovary were removed. The postoperative course was uneventful. Inquiry as to her diet since 1929 seemed to indicate that it was adequate and did not lack vitamin containing foods.

On account of menopausal symptoms she was given treatment with estrogenic substance in oil administered at intervals over a period of three years. The injections were said to have been given twice weekly into the muscles of the upper arm. After about six months of this treatment the patient noticed lumps forming at the sites of injection. She complained of this to her physician and was told that they would disappear in time. Some of them did disappear, but numerous nodules remained. The lesions had been increasing in size and number during the past two years.

When the patient was first seen in the clinic she presented numerous subcutaneous nodules in the lateral portion of both arms, chiefly in the upper third. The masses were fairly well circumscribed and could be moved to a slight extent in the subcutaneous tissue. Pressure on the masses caused a moderate amount of pain, and the patient further stated that at times the lesions would throb and ache without apparent cause. There was no inflammatory reaction on the skin. Some of the masses were as large as 4 or 5 cm. in diameter and they varied from that size down to 0.5 cm. They occurred in chainlike distribution in the subcutaneous tissue.

On March 13, 1940 the tumors were removed from the left arm, and in the following May the remaining more numerous lesions were excised from the right arm. The postoperative course in both instances was uneventful.

Fig. 3—Infiltrate from cyst wall slightly reduced from a photomicrograph with a magnification of 520 diameters.

Gross examination of the tumors revealed numerous cysts embedded in fat. The tumors were not found in the fascial planes or in the muscle but only in the rather thick layer of subcutaneous fat. The cysts varied in size from small globules about 1 mm. in diameter to elongated lesions measuring about 1.5 cm. in length, having a diameter of about 7 or 8 mm.

(fig. 1) Their appearance was that of a simple cyst with a semitransparent cyst wall. When a larger cyst was cut into, oil escaped. The oil was clear, slightly yellowish and unstained. The cysts occurred singly or in groups. Most of the single cysts were the larger ones. Gross evidence of a foreign body reaction was shown by a proliferation of pericytic connective

Fig. 4—Group of small cysts (slightly reduced from a photomicrograph with a magnification of 145 diameters). Flattened lining cells are easily distinguished from fat cells by the variation in size and shape.

tissue extending out into the surrounding fat. This was most definite in the areas where there were numerous small cysts. This proliferation of the connective tissue, binding the surrounding fat to the cyst, made the lesions feel much larger on palpation.

MICROSCOPIC STUDIES

In sections stained with hematoxylin and eosin, the cysts were found to be lined by large flattened cells, most of which had retained their nuclei. The cytoplasm of some of them was finely granular and others contained deposits of yellowish droplets, apparently lipid material. A diffuse infiltration of small round cells, probably lymphocytes, was found about each cyst. This infiltration was more pronounced around the groups of tiny cysts. Occasional plasma cells and a few epithelioid cells were found. The infiltrate was not sharply defined but faded out into the surrounding normal fat (figs. 2, 3 and 4). Many large phagocytic cells were found near the walls of some of the cysts. The nuclei of these cells were eccentrically placed and they had somewhat the appearance of large plasma cells. In the cytoplasm were found numerous, small irregular, refractile golden brown globules (figs. 5 and 6). Sections stained with sudan III showed that the globules were fatty material. These cells, which were interpreted as macrophages, were found most profusely a slight distance away from the cysts and occurred both singly and in masses. An occasional giant cell was found.

COMMENT

The material injected was stated by the patient's physician to have been estrogenic substance in oil. At that time the pharmaceutical house from whom the

material was obtained marketed the estrogenic substance in sesame oil. We are therefore justified in assuming that the tumors were the result of sesame oil injection. Not enough oil could be obtained from our specimens for an attempt at chemical analysis. Furthermore, it is doubtful if an oil of this character could be identified chemically.

The microscopic picture differed from that of the camphor oil tumors in that little or no fibrous encapsulation of the oil droplets was noted and the granulomatous nature of the infiltration was less pronounced. Mook and Wander stated that a diagnosis of tuberculosis had been made in their first case, but such an error was out of the question when our slides were examined. While the infiltration was granulomatous in nature, the scarcity of giant cells and plasma cells and the relatively scanty amount of infiltration excluded definitely the infectious granulomas.

There were numerous cells of a phagocytic character containing droplets of oil (figs 5 and 6) which took sudan III stain. This activity of the phagocytic cells might indicate loss of oil from the cystic areas with encapsulation by the phagocytes.

The tumors were not malignant in the usual sense, but they were invasive locally by seepage of oil from the encysted area and the formation of new tumors in more or less chainlike arrangement along the arm. In this they were quite like the tumors of Mook and Wander.

Fig 5—Group of macrophages which have taken up droplets of fatty material slightly reduced from a photomicrograph with a magnification of 520 diameters

SUMMARY

Tumors occurred in the subcutaneous tissue of the arms of a patient treated with estrogenic substance dissolved in sesame oil.

The tumors were found in the subcutaneous tissues, were in chainlike masses and were invasive, moderately painful and increasing in size.

Microscopically the tumors differed from the Mook and Wander camphor oil tumors in that the fibrous

Fig 6—High power view of a group of macrophages containing fatty material slightly reduced from a photomicrograph with a magnification of 1380 diameters

encapsulation of the oil droplets was far less dense and the granulomatous infiltration was much thinner. The giant cells observed in our case were very scanty in number.

Operative measures were required to give the patient relief and to stop the spread of the tumors.

CONCLUSIONS

Invasive tumors may be produced by injection of estrogenic substance in sesame oil.

It is our belief that the tumors are due to the oil and not to the combination of estrogen and oil.

The injection of oils carrying active drugs and endocrine preparations into the subcutaneous tissues should be avoided.

Subcutaneous and intramuscular oil injections into the arms may produce in some persons painful and disabling tumors. Owing to the anatomicophysiological factors involved, the tumors may increase in size and number by migration of oil droplets, so that operative measures may become necessary.

It is our belief that the muscles of the arms should be abandoned as a site for oil injections of any character and that only the gluteal muscles in the upper outer quadrant of the buttocks should be used for such injections.

3720 Washington Boulevard

ABSTRACT OF DISCUSSION

DR FRED D WEIDMAN, Philadelphia I agree in all respects with the conclusions in this presentation. This condition must be classified as tumor in the same sense that we speak of paraffin oil tumors. The authors have emphasized throughout the fact that there were chainlike extensions from the original focus of the disease. The puzzlement centers around the pathogenesis of the condition. Ordinarily we think of sesame oil, chemically speaking, in the same way that we do of olive oil. The composition of sesame oil except for slightly differing proportions is the same in respect to oleates, palmitates and stearates. It is possible that an adulterant was used in the sesame oil such as the much less expensive paraffin oil. That, of course, is a question. Perhaps some light might have been thrown on this possibility had frozen sections been stained with osmic acid as well as with scarlet red. If it was found that all the fat stained black, that would eliminate the possibility of there being any paraffin oil in the lesions, at least at the time that they were examined. The second possibility is that these lesions might be the result of disorganization of the fat, that is, that they were truly fatty cysts and not necessarily lesions which pathologically were what we call paraffin oil tumors. The fact that the walls of these cysts were so definite inclines one in favor of that hypothesis. There is a long spread of years, though, elapsing between the introduction of the oil and the time of the microscopic examination. It seems as though during that time the products of disorganization should have been absorbed. There is no explanation in this case as to why the sesame oil should have produced these tumors. Sesame oil, like olive oil, of course, in time should become saponified and should become absorbed. Perhaps this is the last straw on which one would have to rely in explaining the development of this lesion. Is it possible that the original focus of fat destruction did not resolve in the way that it should because there was a more or less continuous accumulation of the cholesterol and other nonsaponifiable substances, such as are included in normal subcutaneous fat? Normal subcutaneous fat does not consist purely of olein, palmitin and stearin. There is a certain definite admixture of cholesterol, and it is possible that for some reason or other the lesions did not heal up presently, but, there being a gradual disintegration of the fat, the cholesterol and such insoluble substances remained behind to serve to continue the reaction on the part of the tissue which led to these chainlike infiltrations into the surrounding tissues.

DR FRANCIS A ELLIS, Baltimore This type of tumor is rare. Sesame oil has been used for many years as a vehicle for endocrine products. Dr Emil Novak, who has written many articles on endocrine therapy, and other physicians interviewed have had no personal experience with this type of tumor, and no previous reports were found in the literature or in the *Quarterly Cumulative Index Medicus*. Iodine in sesame oil has been used by roentgenologists. The oil is usually absorbed from the bronchial tree and from body cavities or sinuses. Considering the fact that the patient had received possibly several hundred injections brings up the question of whether some of the oil was absorbed and, if it was, why wasn't more absorbed? This may have been due to accumulative trauma caused by many injections with the replacement of the normal tissue by fibrosis. There was some evidence of increased fibrous tissue about and in the wall of some of the smaller blood vessels which could have lowered the blood supply and made it inadequate for the removal of all the oil. Another reason for the decrease of absorption may be a mild allergic reaction to the oil or to the hormone contained in the oil. The three sections sent to me by the authors showed that the foreign body reaction is far less than that due to the inorganic paraffin and mineral oil tumors. The presence of the foam cell within the fibrous capsule of the cysts demonstrates that the ordinary foam cell is not neoplastic but is due to the absorption or the phagocytizing of the oil by macrophages. There were a number of yellow granules in some of the fibrous tissue that looked like hemosiderin which the authors didn't mention. They were not round, and if they were fat they should have been dissolved out by the dehydrating fat solvents used in making the sections. The word "invasion" may be a poor term to use in describing this type of tumor, as it connotes an aggressiveness or self

propulsion on the part of the tumor, whereas the oil spreads according to physical laws, by the movement of muscles, gravity, and because of the reaction to the foreign body resulting in phagocytosis and fibrosis. Weidman and Jeffries (*Arch. Dermat. & Syph.* 7:209 [Feb.] 1923) demonstrated experimentally that oil could be transported by the lymph of vessels.

DR J LOWRY MILLER, New York I have seen 2 patients this past year, one at the Columbia Medical Center and another at the New York City Hospital Clinic, both of whom had tumors which were clinically typical of paraffinoma. However, both patients had been definitely told that the injection was not paraffin before it was given.

DR ADOLPH H CONRAD, St. Louis We should be on the alert and look for these tumors in the future. I understand that estrogenic substances are now being marketed in peanut oil, and the use of sesame oil has been abandoned. However, other preparations are being used for injection purposes which have as their base sesame oil, therefore it will be well to keep the possibility of tumor formation in mind.

THE PREVENTION OF PULMONARY COMPLICATIONS FOLLOWING THIGH AMPUTATIONS

BY HIGH LIGATION OF THE FEMORAL VEIN

J ROSS VEAL, M.D.
WASHINGTON, D. C.

When, in the course of events, the vascular supply to a lower extremity is so severely damaged by disease that gangrene of the toes or the foot results, it is not surprising that the patient's very life is in extreme jeopardy. Frequently the disease involves the entire vascular system. There is often impairment of function of certain vital organs, notably the heart and kidneys. Procrastination of removal of the dead part invites further bodily injury from pain, infection and toxic absorption. One cannot fail to be impressed by the hazards facing these aging individuals with vascular gangrene, nor can one ignore the sad plight in which the surgeon often finds himself in attempting to relieve the situation. Surgery is a precarious undertaking for amputation must be performed at a sufficiently high level to insure healing of the stump. Uniformly the higher the site of the amputation, the greater the mortality rate.¹ Persons fortunate enough to have a sufficient blood supply of the leg to allow amputation below the knee usually present a favorable prognosis. It is in those cases in which the vascular damage is so great that amputation must be performed above the knee that the problem of surgery becomes most urgent.

There are many factors which affect the outcome of thigh amputations for vascular gangrene.² Chief among these are the age of the patient, the extent and duration of his disease, the exciting cause of the gangrene, local and systemic infection, the state of health of his heart and kidneys, and particularly the postoperative pulmonary complications. These include pneumonia, pulmonary infarcts and massive pulmonary embolism. The incidence of pulmonary complications following thigh amputations is out of all proportions to similar conditions in other fields of surgery. In a

series of two hundred and seventy-five amputations at various levels of the extremities which have previously been reported, 14.9 per cent of the patients died from postamputation pulmonary complications. Practically all these complications occurred in the thigh amputation group. It seems clear then that pulmonary complications following thigh amputations for vascular gangrene present a serious problem for the surgeon.

A closer study of the pulmonary lesions in the aforementioned cases revealed several important findings that seemed to have a direct bearing on this problem. The majority of the lung complications were diagnosed as pneumonia, though the characteristic distribution, the x-ray findings and the clinical course indicated that many were embolic lesions rather than the ordinary forms of pneumonitis. Dissections of the thigh stump in a group of the fatal cases demonstrated that a thrombus had formed in the femoral vein. It was also shown that the thrombus had developed at the distal or ligated end of the femoral vein. In some it extended upward for only a short distance, in others it had propagated into the iliac vein. In those incidences in which the stump had become infected, thrombophlebitis was found involving the lower segment of the vein. These findings indicated that the probable source of the emboli which were responsible for many of the pulmonary complications was from the femoral vein in the stump of the amputated limb. The controlling factor seemed to be the extent of thrombosis in the femoral stump. If the thrombus should propagate upward until a widened portion of the vein was reached there would be an excellent

variation in the extent of the thrombosis in the stump of the femoral vein? An anatomic study of the femoral vein and its tributaries has provided an answer to this question.

The femoral vein is the continuation of the external iliac and is the largest peripheral vein. It begins at the

Fig 1—Venograph of normal femoral vein. Note widening of vein in upper portion.

Fig 2—Venograph showing femoral vein with tributaries. Note extreme widening of femoral at point of entrance of deep profunda.

inguinal ligament and extends down the inner aspect of the thigh through Hunter's canal to become the popliteal vein (fig 1). It receives the deep profunda, the saphenous and several lesser tributaries in its upper third and a variable number of smaller veins in the lower two thirds (fig 2). The saphenous is quite constant in its course, is uniform in size and enters the femoral about $1\frac{1}{2}$ inches below the inguinal ligament. The deep profunda, the major tributary, is quite variable in size and joins the parent trunk at inconstant levels. The branches of the profunda may all unite into a single vein or they may form a double trunk, each entering the femoral at different levels. There is also great variation in the size, number and distribution of the smaller or minor tributaries. While there is a wide variation in the distribution of the tributaries, the femoral presents one of two distinct patterns. In one group there are numerous tributaries, adequate in size, which enter the parent trunk at regular intervals, so that a stepladder arrangement is presented. This type then provides an abundant flow of blood into the femoral at all levels. Ligation at any point fails to cut off an adequate inflow of blood into the femoral stump. In this type thrombus formation is retarded and limited to the distal end of the vein (fig 3A). In the second group the minor tributaries are few in number, are small in size and enter the femoral at wide intervals. This often leaves a long segment of the lower portion of the femoral vein completely devoid of tributaries. In such cases stasis thrombosis is very likely to develop and fill the entire femoral stump following ligation, incident to thigh amputations (fig 3B).

chance for the dislodgment of a portion of the clot and the formation of an embolus. If a shower of small emboli should be thrown off and become lodged in the lungs, the pulmonary lesion would simulate pneumonia. If a larger emboli should be dislodged, infarction or massive embolism would result. There remained one important point: why should there be such a wide

Following these studies I began, as a routine measure, the preliminary high ligation of the femoral vein in all thigh amputations. Since it is not feasible to expose a very long portion of the femoral vein to determine the number of tributaries, it becomes necessary to ligate

Fig 3—Schematic drawing of femoral vein and its tributaries. Thrombus formation after ligation of lower femoral vein. *A* note limitation of thrombus at ligated end when tributaries are abundant. *B* note proper location of thrombus when tributaries are small and few in number.

Fig 4—Technic of ligation of femoral vein in femoral triangle

the vein in all cases in order to obtain security against those that are potentially liable to thrombus formation.

In a preliminary report I outlined the result of this procedure in twenty-seven thigh amputations.³ In this communication I wish to report on eighty thigh ampu-

tations in which this procedure has been used. Because such excellent results have been obtained, I feel that a review of the technic of high ligation of the femoral vein is indicated.

The femoral vein is best exposed in the femoral triangle through a vertical incision placed directly over the vessels (fig 4). The incision should be about 3 inches long and begins 1½ inches below the inguinal ligament. The saphenous vein is identified and followed down to its entrance into the femoral. At this point the femoral sheath is opened and the artery and vein exposed. The vein lies medial to and is partially overlapped by the artery. It is joined by several tributaries at this level, and these must be carefully protected. The femoral artery is retracted laterally and the vein gently exposed just below the entrance of the saphenous. The vein is freed sufficiently at this point to allow the

Fig 5—Venorraphy showing collateral venous circulation after high ligation of femoral vein. Note absence of large trunk.

passage of a ligature. It has been found that the most logical sites for ligation is just distal to the entrance of the saphenous vein. This point is easily located by following the saphenous through the cribriform fascia and ligation at this level insures adequate inflow of blood above the ligature to prevent the formation of a thrombus. There are also abundant channels available for the return blood flow (fig 5). Occasionally the deep profunda joins the femoral very near the sapheno-femoral junction. In such instances it is best to ligate the femoral distal to the profunda. The femoral vein is large and its wall is relatively thin, and care must be exercised in freeing it from its bed. I have found that the passage of the ligature can be facilitated by clamping the vein at the selected site with a hemostat. The vein can then be lifted out of its bed sufficiently to allow the ligature carrier to pass completely around it with ease and safety. Because of the wide variation

3 Veal J R. High Ligation of the Femoral Vein in Amputations of the Lower Extremities. J A M A 114: 1616-1619 (April 27) 1940.

in the size of the vein and the limitation of exposure it has been found that various size ligature carriers are needed. Each tray is set up with a series of curved needles with blunt points. The size needle to fit the particular case is selected and a silk ligature is passed around the vein and securely tied. The incision is then closed in the usual manner and attention is turned to the amputation.

Following amputation a loose dressing is applied and the patient placed under a heat cradle. The stump is not elevated. In practically all cases there has been a prompt readjustment of the venous return blood flow. However, in a few cases the stump has become swollen with pitting edema. Apparently this has been caused by the occurrence of thrombosis in the profunda vein. The edema has always subsided in about ten days and has not produced any further trouble. The wounds have healed as promptly as in those cases in which edema did not occur.

The value of preliminary high ligation of the femoral vein in preventing pulmonary complications in thigh

state, sex and color. The type of amputation was essentially the same in the two series. Low spinal anesthesia was frequently used in both groups and was the anesthetic of choice when not contraindicated. The only essential difference between the two series of cases

Fig 7—Comparison of mortality rate in thigh amputations without and with high ligation of femoral vein. Black zone represents percentage of fatalities in each group. Without high ligation mortality rate is 42.1 per cent. With high ligation mortality rate is reduced to 17.5 per cent.

Fig 6—Incidence of pulmonary complications in one hundred and ten amputations for vascular gangrene.

amputations can best be presented by comparing a series of amputations in which it has been used with a similar group before this measure was instituted. In 1935 I presented a study of one hundred and ten amputations for arteriosclerotic gangrene, in which there were forty-three deaths. Pulmonary complications accounted for nineteen of the fatalities (fig 6). Another series of one hundred and four amputations for the same condition was reviewed at a later date. In this series there were thirty deaths, of which fifteen were the result of pulmonary complications. In one hundred and fourteen thigh amputations performed without high ligation there were forty-eight deaths. Approximately 42 per cent of the deaths were the result of pulmonary complications. In the present series of eighty thigh amputations there were but fourteen deaths (fig 7). Only 1 patient contracted any type of pulmonary complication. She had diabetes, with gangrene of the foot. On the second postoperative day lobar pneumonia set in from which she later died (fig 8). All the patients were indigent and were similar to the first groups with respect to age, duration of gangrene, general physical

was the performance of preliminary high ligation of the femoral vein in the second group of cases. The striking reduction in occurrence of pulmonary complication in this series of eighty thigh amputations by the employment of high ligation of the femoral vein seems to have solved one of the most urgent problems in the surgery of vascular gangrene.

SUMMARY

Pulmonary complications are more frequent following thigh amputations than in any other field of surgery. Many of the pulmonary lesions are embolic in origin. The chief source of the emboli is from the femoral vein in the amputated stump. High ligation of the femoral vein before amputation closes this source of emboli. In two hundred and seventy-five major amputations with-

Fig 8—Mortality in eighty thigh amputations for vascular gangrene with high ligation of femoral vein.

out high ligation of the femoral vein 14.9 per cent of the patients died from pulmonary complications. In eighty thigh amputations with high ligation of the femoral vein there has been only one pulmonary complication.

ABSTRACT OF DISCUSSION

DR GEZA DE TAKATS, Chicago The paper of Dr Veal emphasizes the importance of venous stasis in the formation of thrombi and consecutive emboli. Retardation of venous return has been demonstrated repeatedly on patients after operation or immobilization. The interference with venous return is especially pronounced in the frequently employed Fowler position, during which stasis is produced in the pelvis, in the groin and in the deep and muscle veins of the calves. To overcome this the postoperative Trendelenburg position, maintained from twenty-four to forty-eight hours, is truly a great improvement and can be used for such patients who are unable to carry out simple exercises. Dr Lawrence Petersen has tabulated the mortality following major amputations at the Research and Educational Hospitals. There were 110 major amputations between 1927 and 1942, and 9 patients died giving a mortality of 8 per cent. There was only one death of embolism, of a patient with polycythemia vera who had been treated with leeches up to the fifth day and died on the sixth, after the use of leeches was discontinued. Only 1 patient in this group had a ligation of the femoral vein. In our experience then, pulmonary embolism does not occur frequently after amputations, the incidence being not more than 1 or 2 per cent. Recently I have attempted to study the clotting mechanism of patients by determining their response to heparin. Roughly all individuals fall into one of three groups. Their response to heparin is normal, exaggerated or diminished. In spite of the great importance of venous stasis one should not forget that coagulation of blood is favored in the postoperative state. Heparin or other anticoagulants obviously cannot be given to all postoperative patients, but the endangered group may be picked out by their response to heparin. For such patients all available measures against thrombosis must be carried out with the greatest vigor.

DR EDGAR V. ALLEN, Rochester, Minn. Theoretically there are three possible mechanisms for postoperative venous thrombosis. One of these is an increased tendency of the blood to clot. However in spite of assiduous studies no one has shown conclusively that there exists such an increased tendency after operation. There are some conditions of the blood which predispose to venous thrombosis following operation but the vast majority of patients who are operated on do not show significant changes in the coagulation of the blood after operation. A second factor is the possibility of trauma to veins. I am told that assistants do not lean on a femoral vein during a major operation and that usually no other trauma occurs. Yet it is known that after such operations as cholecystectomy thrombosis of the femoral vein may occur. For those who advocate the theory of trauma, there is some evidence in support as shown by the fact that the incidence of postoperative venous thrombosis following pelvic operations is three times as great as the incidence following operations on the upper part of the abdomen. There is no evidence that this trauma to veins is a significant, persistent cause of postoperative venous thrombosis. The third possibility is the question of slowed circulation of venous blood. How does this fit in with what is known about postoperative venous thrombosis? Similar studies on the circulation of blood in the veins of the upper extremities indicate that there is no significant slowing of the speed of circulation in the upper extremities. That might explain why postoperative venous thrombosis occurs so frequently in the lower extremities and so infrequently in the upper extremities. The fact that the maximum slowing of the venous circulation is on about the eighth to the twelfth postoperative day would fit in well with the observation that that is the period at which postoperative venous thrombosis occurs in the vast majority of instances. This slowed circulation of the blood in the veins would explain also why the administration of thyroid sharply decreases the incidence of postoperative venous thrombosis, and it would explain an observation which I have made that in approximately twelve hundred operations (sympathectomy) for hypertension performed by neurosurgeons there has not been a single instance of postoperative venous thrombosis. Sympathectomy greatly increases the speed of flow of blood through the arteries and through the veins. The evidence suggests that a slowed venous circula-

tion is responsible for postoperative venous thrombosis. A word of caution about the interpretation of statistics. Postoperative venous thrombosis is known to occur infrequently, and it is possible that a large series of patients for whom nothing was done might show no postoperative venous thrombosis merely because it does occur infrequently.

DR LYMAN W. CROSSMAN, New York. In my service at the City Hospital my associates and I have approached the matter of postoperative embolism in what might be considered a physiologic way. We try to prevent the formation of postoperative emboli. Dr de Takats discussed retarding circulation and increasing circulation. What we do is stop circulation by Frederick M. Allen's method of applying a tourniquet to the extremity 6 or 8 inches proximal to the line of cutaneous incision, refrigerating the entire extremity with ice and after two and a half hours perform an amputation with no other anesthesia. At the time of the operation we always find that the blood is fluid. We never see a blood clot. When the stump end is about ready to be closed and the tourniquet is taken off, the blood we see then is always in a liquid form. The examination of the blood drained from the specimen as it is removed has been examined and reported as being normal. Every one of the legs so treated has been examined under the microscope by Dr James Lisa, our pathologist, and he has found no structural change as a result of the long refrigeration or the stasis and pressure brought about by the tourniquet. The tourniquet cuts off all circulation of blood and lymph and all nerve impulses. As most tourniquets are put on there is still an arterial trickle, which allows a flow of warm blood into a refrigerated extremity, and our precautions against this may explain why our patients have never had frost bite. Dr Allen has always emphasized the inhibition of thrombosis by cold, and as we stated in the *Treatics of Surgery* in January, 1942, our group has encountered no instance of thrombosis or embolism with this method. As our series now comprises over a hundred amputations, this experience appears significant.

DR J. ROSS VEAL, Washington, D. C. I have been interested in the freezing of the extremities. Dr Crossman says it is a physiologic action. Speaking of physiology of circulation after freezing, if he cuts off arterial and venous circulation he creates an ideal situation in which thrombosis should occur provided it lasted long enough. Undoubtedly one can amputate an extremity after it is frozen or partially frozen, without pain and the patient may return to the ward and be comfortable and carry on his diet but I don't think that freezing in any way prevents thrombosis. It creates a field in which thrombosis might develop if it persisted long enough. There is one remark I should like to make about high ligation. It is known that clots from other parts of the body may lodge in the lungs. There have been cases in which the embolism came from the heart or some other vein of the body than that of the femoral stump, but I feel that the majority of the pulmonary complications following thigh amputations are embolic and that the emboli arise from the stump of the femoral vein.

High Degrees of Personal Liberty—As a class doctors are independent people. A doctor usually works for himself, he wears no man's collar unless he is hired to work for a medical clinic or unless he is a fashionable practitioner who toadies to the rich and so has passed under the golden yoke. Indeed, if it were not for the responsibility that every physician feels towards his patients, he would be as free as a bird in the air to go and come when he pleased and to take long vacations. If he has any doubts about the high degrees of personal liberty he enjoys in civilian life, a service with our armed forces will soon convince him. Patients may choose any physician they please and dismiss him at their pleasure, but they are not always aware that the doctor has the same privileges, there is no law or rule of medical ethics that compels him to undertake the care of any particular patient, or that prevents him from retiring—gracefully, of course—from the case if the individual proves uncooperative or unbearable. Although this privilege of dismissal is seldom invoked by doctors except as a last resort, it is frequently exercised by patients—Irvine, Frederick C. Safe Deliverance, Boston, Houghton Mifflin Company, 1942.

HYPOCHROMIC ANEMIA IN PATIENTS
WITH DEFICIENCY OF THE
VITAMIN B COMPLEXRESPONSE TO IRON THERAPY WITH AND
WITHOUT YEASTCARL V MOORE, MD
VIRGINIA MINNICH, MS
ST LOUISR W VILTER, MD
ANDT D SPIES, MD
CINCINNATI

Many clinicians have the impression that the response to iron therapy of patients with hypochromic anemia is enhanced if the vitamin B complex is administered concomitantly. Relatively expensive combinations of these two therapeutic agents have been prepared by pharmaceutical houses and are being extensively used. The reasoning behind this dual therapy accepts the recent impression that subclinical or subcritical deficiencies of the B complex are relatively common in the United States¹ and postulates that the circumstances which bring about iron deficiency may lead also to suboptimal intake of vitamins. It is assumed, furthermore, that vitamin deficiency may result either in poor absorption of iron from the intestinal tract or in its defective utilization for hemoglobin synthesis.

These ideas about the interrelationship of iron metabolism and the vitamin B complex germinate from three separate types of scientific evidence. In the first place, many investigators have frequently observed hypochromic anemias in patients with pellagra. Early studies indicated that they were more common than any other type,² but subsequent reports have shown that macrocytic and normocytic anemias also occur among pellagrins and that there is no special tendency toward coexistence with any one type.³

In the second place, Parsons⁴ found that the iron deficiency anemia produced in rats on a milk diet can be cured with yeast as well as with iron and copper, but yeast of low iron content produced less satisfactory hemoglobin increases. Moreover, when Parsons and Hawksley⁵ applied these observations to the treatment of nutritional (iron deficiency) anemia of infants they noticed that the yeast was not nearly as effective therapeutically as it had been in rats, and Ungley⁶ from

observations on adult human subjects with hypochromic anemia concluded that yeast or wheat germ preparations do not raise the hemoglobin level "whether or not the diet had been grossly defective."

In the third place, Fouts and his associates⁷ have demonstrated that in puppies fed a diet deficient in pyridoxine (vitamin B₆) a hypochromic anemia develops which does not respond to iron and copper but improves dramatically when pyridoxine is given. Fouts's observations have been abundantly confirmed in experimental animals,⁸ but instances of a similar anemia in man have not been reported.

Therefore, even though there have been suggestions that vitamin B and iron metabolism are intimately related the evidence is not conclusive except for pyridoxine in experimental animals, and there are no satisfactory data in the medical literature to support the idea that administration of the vitamin B complex increases the therapeutic effectiveness of iron in man. The present investigation was undertaken in an attempt to clarify this point. Results will be presented under the following headings: (1) occurrence of hypochromic anemias in patients with deficiency of the vitamin B complex, (2) response of these patients to iron therapy alone and (3) their response to iron when supplemental amounts of the B complex were also given.

MATERIAL AND METHODS

Fifty adult patients with hypochromic microcytic anemia were found in the Nutrition Clinic of the Hillman Hospital in Birmingham, Ala., during the summers of 1940, 1941 and 1942. Only 5 of them were men. Almost all had been on a diet extremely low in the vitamin B complex⁹ and, with but few exceptions, had had recurring deficiency diseases for years. Thirty-two of the 50 patients had clinical manifestations of a deficiency disease at the time of this study, 15 showed evidences of inadequacy of more than one member of the B complex. The diagnosis of each deficiency disease was made on the basis of clinical manifestations, since the levels of the various B vitamins in blood are not sufficiently altered in most cases of avitaminosis to have diagnostic significance.¹⁰ Niacin (nicotinic acid) deficiency was recognized by the presence of pellagrous glossitis and dermatitis. The criteria accepted for the diagnosis of ariboflavinosis were the presence of cheilosis or cheilosis accompanied by lesions in the eye,¹¹ magenta tongue and sharklike skin about the nares. Multiple neuritis, confirmed in a few instances by biopsy of a peripheral nerve, was accepted as the principal clinical evidence of thiamine deficiency. However, patients with multiple neuritis also frequently exhibited

These studies were aided by a grant from Anheuser-Busch, Inc., St. Louis.

the emotional instability and nervousness described by Frostig and Spies¹² and by Williams and Mason¹³

Determinations of the erythrocyte count, hemoglobin value and reticulocyte percentage were made every twenty-four or forty-eight hours on those patients to whom iron was given, transportation difficulties prevented a few subjects from reporting for observation oftener than once each week. The hemocytometers and blood counting pipets used were standardized by the U S Bureau of Standards. Hemoglobin determinations were made by the Evelyn technique¹⁴. Reticulocyte preparations were made with both wet and dry methods¹⁵. Serum iron values were determined by the method of Moore, Minnich and Welch¹⁶.

HYPOCHROMIC ANEMIA IN PATIENTS WITH HYPOVITAMINOSIS B

Reference has already been made to the fact that hypochromic anemia has been observed by a number of investigators in patients with pellagra. However, all these surveys were made before ariboflavinosis was distinguished from the niacin deficiency aspects of pellagra and before it was recognized that multiple neuritis is also frequently a part of that syndrome. It is of interest, therefore, to record that hypochromic anemia was found with all three types of deficiency: niacin deficiency in 23 (46 per cent), ariboflavinosis in 20 (40 per cent), peripheral polyneuritis in 7 (14 per cent) and no recognizable deficiency in 18 (36 per cent). These figures total more than 100 per cent because two or all three types of deficiency were present in 15 patients. This distribution of these three deficiency diseases correlated well with their incidence in the Hillman Nutrition Clinic as a whole during these three summers of study. There was, therefore, no tendency for the hypochromic anemia to occur specifically with niacin, riboflavin or thiamine deficiency.

These results are in accord with published clinical and animal investigations. Williams and Mason,¹³ for instance, noted in their cases of induced thiamine deficiency that any anemia that developed was of moderate degree and macrocytic. Patients with pellagra have macrocytic anemia at least as frequently as hypochromic,³ and animals in which niacin deficiency is produced have not been observed to develop hypochromia of their red cells. Animals deficient in riboflavin apparently do not develop a hypochromic anemia¹⁷ although administration of this vitamin does increase the rate of hemoglobin production by the anemic dog¹⁸. It is difficult to evaluate the literature regarding the association of hypochromia with ariboflavinosis because cheilosis, the most frequent manifestation of riboflavin deficiency, apparently occurs from other causes, particularly as the result of poorly fitting artificial dentures¹⁹. It is noteworthy that many of our patients were young (50 per cent under 40 years), 11 of the 20 with cheilosis had

artificial dentures. In addition, fissures at the corners of the mouth have been described as one of the clinical features of hypochromic anemia²⁰. There are two possible explanations for this: (1) either cheilosis may occasionally be caused by iron deficiency or (2) the patients with cheilosis had an unrecognized ariboflavinosis. The latter explanation appears possible, since all the reports describing fissures at the angles of the mouth as one of the manifestations of hypochromic anemia appeared before cheilosis was related to riboflavin deficiency. Certainly there has been abundant experience in the Nutrition Clinic of the Hillman Hospital that (1) the cheilosis seen there responds to riboflavin administration and (2) most patients with cheilosis do not have an anemia. Several of the patients with cheilosis and hypochromic anemia included in this study experienced temporary improvement of their lesions at an angle of the mouth during iron therapy, but the fissuring always recurred and responded subsequently to riboflavin. It would appear, therefore, that the cheilosis among these patients resulted from riboflavin deficiency. Murphy and Damargian²¹ came to a similar conclusion about 1 patient whom they observed.

Particular attention, however, should be given to the possibility that hypochromia in some of these 32 patients might have been caused by pyridoxine deficiency. Reference has already been made to the work of Fouts and others² which demonstrated that dogs fed a diet inadequate in pyridoxine develop a hypochromic microcytic type of anemia which does not respond to iron and copper but improves promptly when pyridoxine is given. These dogs, in addition, had a high serum iron level,² in contrast to the low serum iron values obtained when a state of iron deficiency exists²¹. If any of the patients included in this study had a pyridoxine deficiency, therefore, and if the manifestations of this deficiency are the same in man as in the experimental animal, then our patients should (1) have had a high serum iron value before therapy was begun, (2) have shown no hemoglobin rise when iron was given and (3) have responded specifically to pyridoxine administration. Not one of these three things was true. All patients had initial serum iron values below 0.050 mg per hundred cubic centimeters, the range usually found in subjects with an iron deficiency and distinctly below the normal average of 0.09 to 0.12 mg per hundred cubic centimeters²⁴. All patients responded with a reticulocyte increase and hemoglobin rise when iron was given. Pyridoxine failed to produce these results. Therefore, if pyridoxine deficiency was present in any of the patients studied, it was not characterized by a hypochromic anemia.

Three factors seemed to be operative in the production of the hypochromic anemia found in this series of cases: (1) chronic blood loss, (2) lowered gastric acidity and (3) inadequate intake of iron. With three or four exceptions, all patients were shown to have either increased menstrual loss of blood or bleeding from the intestinal tract (hemorrhoids, hookworm infection, rectal stricture or peptic ulcer). Gastric analysis made on 10 of the subjects revealed either achlorhydria

or hypochlorhydria in all but 1 instance. This lack of gastric acidity undoubtedly diminished the ionization and subsequent absorption of food iron.²⁵ Analysis of the diets eaten by patients of the Hillman Clinic have shown them to be low in iron.⁹ It seems justifiable, therefore, to conclude that hypochromic anemia has no special pathogenic relationship to any of the types of vitamin B deficiency recognized to date in man and that when it occurs in association with these deficiencies it has resulted from combinations of such factors as blood loss, hypochlorhydria and poor food intake.

RESPONSE TO IRON THERAPY OF PATIENTS WITH HYPOCHROMIC ANEMIA AND DEFICIENCY DISEASE

The second part of this study concerns the response of 10 patients with hypochromic anemia and deficiency disease to the oral administration of iron alone. No other medication was permitted, vitamins of the B complex were rigidly avoided and the subjects were instructed to make no changes in their diets. The usual therapeutic doses of ferrous salts were given (exsiccated ferrous sulfate 0.8 Gm daily) except in 2 instances (cases 3 and 6) when, for purposes of a separate investigation, the dose of ferrous sulfate was limited to 0.16 Gm daily during the first twenty-one days. Data indicating the effectiveness of therapy are summarized in table 1. A reticulocyte peak of 6 per cent or more was observed in each case on the seventh to the fourteenth day of iron administration. The 6 patients with an initial hemoglobin value of 7.8 Gm or less showed a daily rise in hemoglobin of from 0.13 Gm to 0.22 Gm per hundred cubic centimeters except in 1 young girl (case 4) with fever from a chronic pelvic infection, and it is well known that fever and infections interfere with the effectiveness of anti-anemic substances. Her daily rise in hemoglobin during a fifty-four day period was only 0.1 Gm per hundred cubic centimeters. The average daily increase in the 6 cases was 0.163 Gm, or 1.06 per cent (15.4 Gm considered as 100 per cent) for each 100 cc of blood. This figure compares favorably with the average rise of 1.175 per cent previously reported for ferrous sulfate.²⁶ For the 4 subjects with an initial hemoglobin above 7.8 Gm, the rate of hemoglobin increase was somewhat slower—0.087 Gm, or 0.565 per cent per hundred cubic centimeters a day. This average was lowered considerably by a woman (case 10) with rectal stricture who had diarrhea during most of the observation period. Even so, the rate is comparable again to the reported figure of 0.65 per cent.²⁶ It may be concluded, therefore, that the oral administration of ferrous sulfate to these 10 patients was therapeutically effective in bringing about satisfactory hemoglobin regeneration.

During the period of iron therapy, the lesions of the deficiency diseases usually remained relatively stationary. In a few instances there was slight improvement, particularly in the cutaneous lesions of patients with pellagra, but to no greater degree than is frequently seen near the end of the summer in the Nutrition Clinic of the Hillman Hospital. In several instances the lesions became worse. However, after these observations had been completed specific vitamin therapy with niacin, riboflavin or thiamine never failed to correct the clinical manifestations of the deficiency.

Case 3 in table 1 will be presented in detail.

CASE 3—A woman aged 38, a native of Alabama had experienced her first attack of pellagra at the age of 24. Since then she had had at least mild symptoms of deficiency disease nearly each year. She was observed carefully in the clinic during the summer of 1939, at which time she had (1) tenderness of the muscles of her legs with severe burning of the soles of her feet and skin over her face, neck, arms and legs, (2) nervousness and emotional instability, (3) cheilosis, (4) burning sublingually and of her tongue and (5) a fiery red edematous tongue. Her mouth felt 'scalded' and even water was difficult to drink. The consequent difficulty in eating accentuated the inadequacy of her already poor diet. Riboflavin, administered first, corrected the cheilosis but failed to influence the other signs and symptoms. When thiamine hydrochloride was also given the paresthesias disappeared, her appetite improved and her emotional instability was less evident, but the glossitis persisted. Finally niacin was given and her mouth symptoms improved. Vitamin therapy was discontinued after several weeks.

When she reported again in 1940, the glossitis, cheilosis and paresthesias had returned. She had a "glimmer in front of

Chart 1 (case 3) — Response to iron therapy of a patient with hypochromic anemia, niacin deficiency, ariboflavinosis and multiple neuritis.

her eyes" and felt at night as if something was obstructing her vision. Fatigue was pronounced. She also complained that her finger nails were brittle and stated that, while her menses began regularly at twenty-eight to thirty day intervals, the menstrual flow was excessive and frequently lasted for two to three weeks.

Physical examination was essentially negative except for the cheilosis, glossitis and pigmentation of the skin of both arms and legs. Pelvic examination showed only an old laceration of the cervix. Reflexes were physiologically active. Laboratory studies revealed a hypochromic microcytic anemia with an erythrocyte level of 3,960,000 cells and a hemoglobin value of 5.9 Gm. Her red cells were microcytic (51 cubic microns) and hypochromic (mean corpuscular hemoglobin concentration of 28 per cent). The Kahn reaction was negative.

On June 21, 1942 she was given ferrous sulfate 40 mg four times a day. One week later a characteristic pellagrous dermatitis made its appearance on both ankles. Meanwhile, a reticulocyte response developed, a peak value of 10.6 per cent was reached on the eighth day (chart 1). After three weeks on this relatively small amount of iron the dose was increased to 200 mg of ferrous sulfate four times a day. The red blood cell count returned to normal and the hemoglobin level rose to 13.7 Gm, a daily increase of 0.2 Gm per hundred cubic centimeters of blood. Coincident with the improvement in

THERAPEUTIC EFFECTIVENESS OF IRON SUPPLEMENTED WITH YEAST IN PATIENTS WITH HYPOCHROMIC ANEMIA AND DEFICIENCY OF ONE OR MORE OF THE B COMPLEX VITAMINS

While the foregoing observations establish the fact that patients with hypochromic anemia and a concomitant deficiency of one or more vitamins of the B complex

teen days and immediately thereafter iron supplemented with brewers' yeast for an additional fourteen days. This was done for two reasons. If the yeast increased the effectiveness of iron therapy then (1) a second reticulocyte response should occur during the second therapeutic period and (2) the rate of hemoglobin regeneration should be more prompt than when iron alone was given.

Data on these 4 patients are presented in table 2. Iron was given as 13 Gm of ferrous gluconate daily. Brewers' yeast²⁷ was administered in 25 Gm doses three times a day. No secondary reticulocyte rise developed following the addition of yeast, and the average daily hemoglobin increase was not greater than in those patients to whom iron alone was given (table 1). The average rate for the 2 subjects with initial hemoglobin values below 7.8 Gm was 0.17 Gm, or 1.1 per cent per hundred cubic centimeters of blood a day, and for the 2 with initial levels above 7.8 Gm, 0.099 Gm, or 0.064 per cent a day. There was, therefore, no evidence that the brewers' yeast had any additive effect in promoting a more rapid hemopoietic response.

The clinical abstract of case 11 (table 2) follows.

CASE 11—V. C., a housewife aged 29, a native of Alabama, felt well until the summer of 1940, when she "passed stomach worms" in her stool. She complained of fatigue, occasional bouts of fever and diarrhea. She delivered her third child in January 1942. During the last several months of her pregnancy she noticed shortness of breath, unusual weakness, soreness of her tongue, vertigo, burning and aching of her eyes and anorexia. These symptoms persisted after her pregnancy had been terminated and she began to lose weight. On several occasions she noted that her stools were black. There was constipation and a nocturia of two to three times. In May a pellagrous dermatitis appeared on her arms and hands. Her diet contained no green vegetables, no fresh fruit, no milk, no meat except salt pork and only an occasional egg. There had been no menstrual irregularities.

On physical examination the patient was pale and well developed. Her skin was dry and pigmented on her neck, face and arms. A scaly pellagrous dermatitis was present on the arms and legs. The tongue was pale slick and atrophic. There were no fissures at the angles of her mouth. The head and neck otherwise were normal, as were also her chest and abdomen. The heart was not enlarged, sounds were of good quality and no murmurs were present. The blood pressure was 100 systolic and 70 diastolic. The pulse was regular with a rate of 72. Reflexes were physiologically active and equal.

Laboratory studies showed 3,790,000 red blood cells, hemoglobin value 7 Gm, hematocrit 26 per cent and reticulocytes 2 per cent. Erythrocytes were microcytic (67 cubic microns) and hypochromic (27 per cent mean corpuscular hemoglobin concentration). The urine was normal except for a trace of albumin. The Kline reaction was negative. The stools contained occult blood, but no parasites or their ova were found.

From July 13 to Aug. 6, 1942, she was given 0.325 Gm of ferrous gluconate four times a day. On the ninth day a reticulocyte peak of 6.2 per cent was reached. Twenty-five Gm of brewers' yeast taken three times a day was added as a supplement to the iron on July 17. No secondary reticulocyte increase was noted. The red blood cell count and the hemoglobin level rose to 4,810,000 and 12.7 Gm respectively. With iron alone the patient's anorexia and some fatigue disappeared, but the dermatitis did not disappear until July 31, fifteen days after yeast had been added.

These results indicate that brewers' yeast does not add to the effectiveness of iron therapy for hypochromic anemia. It is felt that much of the desire to combine other substances like copper, liver and brewers' yeast with iron for the treatment of hypochromic anemia in adult patients has resulted because iron is frequently used in the treatment of anemias which are not hypochromic. Hypochromia is the one readily detectable evidence of iron deficiency, and iron has therapeutic value only when a state of iron deficiency exists.²⁸ It has never been shown to be effective in the treatment of normochromic anemias with or without supplements.

We have never seen an adult patient with hypochromic anemia who would not respond satisfactorily to iron alone unless fever, infection or a severe diarrhea was also present.

SUMMARY AND CONCLUSIONS

1. Thirty-two patients with hypochromic anemia were observed in whom niacin deficiency, ariboflavimosis or multiple neuritis was also present. Fifteen of these subjects had lesions of more than one type of deficiency disease. There was no tendency for hypochromic anemia to occur specifically in association with any one of these three deficiency states.

2. If pyridoxine deficiency occurred among the patients in the Nutrition Clinic of the Hillman Hospital it was not accompanied by hypochromic anemia with high serum iron levels.

3. Iron therapy alone produced a satisfactory reticulocyte response and rate of hemoglobin generation.

4. Brewers' yeast had no demonstrable effect in increasing the efficacy of iron therapy.

Chart 2 (case 11).—Effects of iron and brewers' yeast on a patient with hypochromic anemia, niacin deficiency and multiple neuritis.

5. The degree and type of vitamin B complex deficiency seen among these patients did not detectably interfere with iron absorption and utilization.

ABSTRACT OF DISCUSSION

DR WILLIAM DANESHER, Boston. The paper is one of the first to debunk the vitamins. Vitamin therapy has become almost an obsession. Almost every case of anemia and almost any other condition which might be mentioned is now being treated with vitamins. To have Dr. Moore show that the vitamin B complex is not essential in the treatment of hypochromic anemia represents one of the first steps to make the pendulum swing the other way. Iron, liver extract and the vitamin B complex are essentially intracellular enzymatic materials which have to do with oxidation-reduction mechanisms within the body cells. Deficiencies in iron, liver extract and vitamin B complex may result in similar objective phenomena relating to the skin, the tongue, the corners of the mouth and the fingernails. Cheilosis is considered by some to be pathognomonic of riboflavin deficiency, although I believe this is an exaggeration. About twelve years ago when we reported our cases of chronic "idiopathic" hypochromic anemia, we directed attention to lesions at the corners of the mouth then called "la perleche." A deficiency in various types of intracellular enzymatic substances (fractions of the vitamin B complex) may produce changes at the mucocutaneous junctions at the corners of the mouth. I should like to know if Dr. Moore has any "yardsticks" by which

²⁷ The brewers' yeast powder contained 0.18 mg of thiamine, 0.06 mg of riboflavin and 0.4 mg of niacin per gram.

²⁸ Pound Table Discussion on the Therapeutics of Anemia. *J. Pediat.* 17: 547 (Oct.) 1940.

to tell whether patients with cheilosis actually have ariboflavinosis or some other deficiency. It is certain that some persons not only have a vitamin B complex deficiency but an iron deficiency as well. Doctors frequently ask "Since combined deficiencies are common, why not give a combination of the various drugs?" I always like to combat that. I like to reserve liver extract for pernicious anemia (liver extract deficiency), vitamin B complex for vitamin B deficiency and iron for hypochromic anemia. The vitamin B complex, as Dr Moore and his collaborators pointed out, has apparently nothing to do with iron deficiency. If one has a case of chronic hypochromic anemia it should be treated with adequate doses of iron. The addition of vitamin B complex has been without value, in my experience.

DR CARL V. MOORE, St. Louis. What Dr Dameshek has said about the difficulties of diagnosing riboflavin deficiency is correct. It so happened that, during a part of the time that these studies were being made, determinations of riboflavin were made on samples of blood and muscle obtained from some of the patients. These determinations did not make the diagnosis more definitive. Therefore we are forced to stay in support of the diagnosis of riboflavin deficiency in these people who had cheilosis that (1) their cheilosis was not improved when they were given iron alone and that (2) their cheilosis did disappear when subsequently they were given adequate therapeutic doses of riboflavin. I realize how unsatisfactory it is to make a diagnosis of a disease on the basis of response to therapy but at the present time, it seems to me, therapeutic response is the best criterion we have for substantiating the diagnosis of riboflavin deficiency.

EPIDEMIC KERATOCONJUNCTIVITIS

CLINICAL AND EXPERIMENTAL STUDY OF AN OUTBREAK IN NEW YORK CITY

FURTHER OBSERVATIONS ON THE SPECIFIC RELATIONSHIP BETWEEN A VIRUS AND THE DISEASE

MURRAY SANDERS, MD

F. D. GULLIVER, MD

L. L. FORCHHEIMER, MD

AND

R. C. ALEXANDER, MS

NEW YORK

Information concerning epidemic keratoconjunctivitis has, for the most part, been limited to clinical descriptions. Because the incidence of the disease in the United States has increased rapidly since its appearance in California two years ago, further information on the status of the etiologic agent and its mode of spread is desirable.

Initial efforts in this direction were made when, early in 1942, a few cases were observed in New York City and a virus was isolated.¹ The present investigation deals with 80 cases examined and treated at the office of a local ophthalmologist. These cases were studied from the clinical, epidemiologic and experimental aspects.

CLINICAL ASPECTS

While epidemic keratoconjunctivitis is certainly a distinct clinical entity, and while it has a well defined symptomatology in fully developed cases, it should

be stressed that the beginning signs and symptoms are often indefinite and vary so greatly that in the early stages the disease may be easily confused with other acute eye diseases, especially acute conjunctivitis. Since the onset is so variable, it is suggested that the possibility of epidemic keratoconjunctivitis be considered in any case of acute conjunctivitis which does not show improvement after ten days (especially if there is little or no secretion present).

In the group of cases under discussion, the signs and symptoms which were the basis for diagnosis were as follows. Initially there was a hyperemia and swelling of the palpebral conjunctiva. Very often the conjunctiva resembled that seen in ordinary follicular conjunctivitis. At this stage the patient complained of irritation, a "sandy feeling" as if a foreign body was present, and tearing. After twelve to thirty-six hours the bulbar conjunctiva also became congested and hyperemic, and varying degrees of edema of the lids (particularly of the upper lid) were often present. Occasionally the amount of edema was so extreme that it was difficult to open the eyes for inspection. In a small number of cases pseudomembranes appeared, usually on the conjunctiva of the lower lid. When these pseudomembranes were removed with a swab, bleeding points were revealed.

The intensity and sequence of appearance of the objective signs mentioned varied greatly in the cases studied. It must be stated that the initial symptoms had no bearing on the duration or intensity of the disease. As a matter of fact eyes which showed violent symptoms in the beginning occasionally cleared up fairly rapidly and without resultant visual impairment.

In addition to the clinical picture described, two conditions were so often present that together they were considered pathognomonic for epidemic keratoconjunctivitis in this study.

1. There was practically no discharge from the conjunctiva.

2. Shortly after the onset of the inflammation of the conjunctiva a swelling of the preauricular nodes appeared. Occasionally the submaxillary and cervical nodes also were enlarged.

In 34 of the 80 cases, i. e. 42.5 per cent, the second eye became involved after a varying period of time. As a rule the course of the disease in the second eye was much shorter and the inflammation considerably less than in the first eye.

Corneal Involvement.—This was a frequent and serious complication. It occurred in many cases without any signs of pain or photophobia or other subjective or objective warning. Corneal infiltrations developed in 42 of 80 cases, or 52.5 per cent. The time interval between the onset of the disease and the involvement of the cornea varied between five and thirty-eight days, with an average period of fourteen days. Usually the first sign of corneal involvement was the appearance of several tiny punctate infiltrates of the cornea in the subepithelial layer. In no case did abrasions, superficial ulcers or lesions of the surface epithelium occur at the points where the infiltrates later developed. The corneal epithelium was always intact and did not stain with fluorescein. In the majority of cases the corneal infiltrates were located on the exposed part of the cornea, i. e. within the confines of the palpebral fissure, and usually in the pupillary area.

It has been asserted by some observers that an eye affected with epidemic keratoconjunctivitis should be closed in order to prevent the development of erosions.

Aided by grants from the Warner Institute for Therapeutic Research (Division of the William R. Warner & Company) and from the John and Mary R. Markle Foundation.

From the Departments of Ophthalmology and Bacteriology, Columbia University College of Physicians and Surgeons and the Institute of Ophthalmology, Presbyterian Hospital.

This investigation was carried on in informal collaboration with the Commission on Neurotropic Virus Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army.

¹ Sanders, Murray. Epidemic Keratoconjunctivitis. Arch. Ophth. 28: 581 (Oct.) 1942. Sanders, Murray, and Alexander, R. C. J. Exper. Med. 77: 71 (Jan.) 1943.

or of superficial ulcers and consequently of corneal infiltrates. Following this suggestion, the eyes of a considerable number of patients were kept covered for a long period of time, but this did not prevent the development of corneal lesions. Once the cornea became involved, the opacities failed to absorb to any considerable degree and were present after a period of six months. For this reason it seems likely that in most of the cases observed in this series, unlike those studied elsewhere,² absorption of corneal opacities may not take place.

In spite of the fact that corneal opacities were present, however, many of the patients still enjoyed 20/20 vision. However, in 14 of the 42 cases with corneal involvement impairment of vision from 5 to 15 per cent was observed. The degree of impairment of vision in these cases was distributed as shown in table 1. This evaluation of visual impairment was possible because records of patients' vision both before and after the disease were available, and routine visual examinations were carried out at the patients' first visits.

Systemic Manifestations—Since in previous experience with epidemic keratoconjunctivitis an occasional patient had complained of systemic symptoms, an attempt was made to determine as exactly as possible what systemic symptoms, if any, were manifested by the patients in this investigation, and whether these manifestations were related to the ocular disease. Careful questioning of each patient revealed that headache and "night pain," fever and malaise were more or less common.

By far the most common symptom was the headache which 49 patients (61.2 per cent) described. As a rule, the headache was moderately severe and was not relieved by analgesics. The most frequent description was of a dull pain extending over the fronto-occipital areas. The headache, which appeared shortly after the onset of conjunctivitis, lasted two to three days in "moderate" cases and about four days in "severe" cases. The 9 patients with severe headaches, and 4 of the patients with moderately severe headaches, could not sleep because of this symptom and consequently described it as a "night pain." The patients felt quite certain that the headaches were associated with the keratoconjunctivitis.

The extent to which other symptoms were present is seen from the following data. Five patients reported that they had been definitely feverish shortly after the onset of the conjunctivitis, but no record of rise in temperature was kept by either patient or physician. Twelve patients apparently suffered from moderate malaise and 14 from severe malaise, making a total of 26 cases, or 32.5 per cent. All these patients were quite definite in their statements and described the symptom as "not feeling well" or having an "achy feeling."

Preauricular lymph node enlargement is a diagnostic criterion of epidemic keratoconjunctivitis, but because of its relationship to systemic involvement and immune response it may be considered with the systemic manifestations. In the present series only 5 patients did not have distinctly palpable regional nodes at the time they were seen by the examining physician. The enlargement and tenderness of the nodes persisted from one week to several months after the onset of the

conjunctivitis. In 56 cases (70 per cent) there was moderate enlargement and the node diameters varied from approximately 1 to 1.5 cm. In these cases involvement was generally limited to the preauricular glands. In addition, definitely enlarged glands with diameters of approximately 2 cm were present in 17 cases. Other regional lymph channels were commonly involved when the preauricular gland was very large and in most of the latter 17 cases the submental and cervical nodes also were palpable. It was in this group that malaise was most common.

It might be well to point out at this time that 3 patients who had severe systemic symptoms had a mild ocular disease. On the other hand 19 patients had both severe systemic and severe ocular symptoms. It should be noted that no patient had a severe ocular disease without accompanying systemic symptomatology.

Disability and Course of the Disease—Disability varying from one to eight weeks was suffered by 57 patients (71.2 per cent). In table 2 the loss of time from work is shown; these figures do not, of course, reveal the loss of efficiency, which in many cases was present for periods longer than those indicated.

15 per cent	6

TABLE 2—Loss of Time from Work

Disability in Weeks	Number of Patients
0	23
1	5
2	15
3	10
4	10
5	8
6	2
8	1
Total	50 cases

It is of interest to note that, of the 57 patients who suffered disability, 24 had no corneal involvement. More than half of this group of 24 (16 patients) were kept from work because of systemic reactions and general discomfort which could be traced to the eye. The remaining 8 patients were kept from work only because of ocular discomfort. The majority of patients who suffered one or two weeks' disability is to be found in the group who complained of systemic symptoms without corneal involvement (15 of 20 patients), whereas those patients (27 of 37) who lost three, four, five, six or eight weeks from work had, for the most part, severe corneal involvement.

In general we appeared to be dealing with a moderately severe outbreak as judged by disability, systemic involvement and ocular symptomatology. In this respect it should also be noted that 28 patients developed a bilateral keratoconjunctivitis, the second eye of 21 of the 28 patients (75 per cent) becoming involved within a three to seven day period after the appearance of symptoms in the first eye.

It was impossible to compute the mean duration of epidemic keratoconjunctivitis in the present study because many of the patients are still under observation, and others did not return to the physician's office when they felt better or when they returned to work.

² Hogan M J and Crawford J W. *Am J Ophthalmol* 25: 1059 (Sept.) 1942. Rieke F E. *Epidemic Conjunctivitis of Presumed Virus Causation*. J A M A 119: 942 (July 18) 1942.

Treatment—It was found that strong antiseptic solutions did more harm than good. A mild solution of boric acid or a mild solution of zinc sulfate gave temporary subjective relief. Large doses of sulfathiazole and sulfadiazine given orally, and sulfathiazole applied locally, had no effect. Intradermal injection of tuberculin did not hasten the absorption of corneal infiltrations.

Chart 1—Incidence of epidemic keratoconjunctivitis. Each number represents a patient.

The routine procedure which appeared to give some relief consisted of cold compresses applied locally and mild solutions of boric acid or zinc sulfate instilled in the eye after each compress. Ethylmorphine hydrochloride 0.5 to 2 per cent for local use on the eye was prescribed routinely in order to bring about absorption of the corneal opacities. In addition to this local treatment, riboflavin was given by mouth, usually 15 mg a day. As stated previously, no noticeable absorption resulted in any case.

EPIDEMIOLOGIC ASPECTS

In analyzing the cases which constituted the present outbreak, the first observation of possible significance was that the initial case was observed in the office on Jan. 27, 1942, with a history of keratoconjunctivitis of three days' duration. This appeared to be a mild case, without corneal involvement. The acute phase lasted until February 17 when the patient was considered 'cured' and was discharged. In spite of the apparent mildness of the infection the ocular discomfort and headaches were sufficiently pronounced so that the patient did not work for two weeks. As can be seen from chart 1, the next 4 cases occurred in a rather sporadic fashion, and it was not until fourteen weeks after the appearance of the first case that a distinct increase in the incidence of the disease was noted, with 6 new cases appearing during the week of April 26 and 5 new cases in the week of May 3. From that point on, the incidence of epidemic keratoconjunctivitis among patients in this study fluctuated. It reached a peak during the month of August, and at this point the aid of the Ophthalmological Institute of Presbyterian Hospital was enlisted. The incidence then fell rapidly to only 1 new case during the week of September 13. No new cases have developed in the office practice since that date.

Since it was noted that epidemic keratoconjunctivitis appears in shipyards and industrial centers, an effort was made to classify the patients according to occupations. It was found that there was a wide variety of occupations (table 3). Although the same industrial company is apparently represented frequently, the individual cases were scattered in subplants and branch offices throughout the city, and, as far as could be

determined, the patients had absolutely no contact with one another outside the physician's office.

Further investigation revealed that only 10 of the 80 patients (12.5 per cent) had come to the office because of epidemic keratoconjunctivitis. The other 70 patients originally complained of foreign bodies, ocular abrasions and wounds (usually of the cornea), acute or subacute conjunctivitis and corneal ulcers. Seven cases fell into a miscellaneous group of symptoms which included thrombosis of the central vein, chlamydia, subacute conjunctival hemorrhage, allergic acute conjunctivitis and lime burn. As can be seen from table 3, the various original pathologic conditions were fairly well distributed throughout the different occupations.

It appears that preceding trauma or inflammation may predispose an eye to the subsequent attack of epidemic keratoconjunctivitis but it is obvious that these conditions are not the only factors involved since even during the epidemic period only a small proportion (average 10 per cent for any one month) of patients treated at the office for ocular trauma or inflammation developed epidemic keratoconjunctivitis.

The epidemiologic data have been presented because little or no definite information is available concerning the mode of spread of epidemic keratoconjunctivitis. It is interesting to note, however, a possible significant sequence of events in connection with certain patients in this study.

Patient 58, the first one with epidemic keratoconjunctivitis seen, appeared in January. Analysis of the visits of patient 58 revealed an overlapping with the visits of patient 64 and 64's visits overlapped with those of the patients who next developed the disease, i.e., 44, 22, 57 and 45 (chart 2). It should also be noted that cases 64 and 44 were mild and occurred early in the period before the pronounced increase in incidence, whereas this increase took place shortly after the appearance of two severe cases, 57 and 22.

Another fact which may be interjected at this point is that patient 64, who formed a connecting link

Chart 2—Visits of patients to doctor's office. Each number represents a patient. An encircled number represents a patient who had epidemic keratoconjunctivitis when first seen by the physician. In the lower part of the graph, each dot represents one visit to the office by the patients indicated in the column on the left.

between the original one 58 and the patients who next contracted the disease, did not develop epidemic keratoconjunctivitis until nine weeks after his appearance at the office. Did he then harbor the virus without evidence of infection and serve as a possible focus of infection for others or did he merely become

3 Patient 35 (chart 1) is not included in this sequence of those whose visits overlapped because this patient did not return to the office after the diagnosis of epidemic keratoconjunctivitis was made.

infected at a later date? For the present the answers to this and other questions must remain entirely in the field of speculation. As far as can be determined, hygienic procedures were followed at the office, so that, presumably, contaminated hands did not touch fresh patients. Therefore it is not possible to determine the exact mode of spread of the disease in the present instance.

In spite of this limited information, the present epidemiologic data may be of value in two respects.

1 It is obvious that physicians who see patients with ocular inflammation should continue to observe meticulous hygienic precautions since they are manifestly dealing with a large number of individuals who may be susceptible to epidemic keratoconjunctivitis, although just what the individual predisposing factors are remains to be determined.

2 From an analysis of patients' visits, it is obvious that early diagnosis of epidemic keratoconjunctivitis

described elsewhere. One series of tissue cultures were kept at 37 C for three days and one series at room temperature for nine to ten days. At the end of the periods designated, groups of 6 mice were injected with tissue culture material intracerebrally (0.03 cc) and also intraperitoneally (0.1 cc). If this first passage from tissue culture to mouse was negative or questionable, i. e. if mice did not develop definite symptoms following inoculation, no further attempts were made toward the isolation of a causative agent. In other words, the present experiment was a test of how practical the tissue culture technique is for a simple isolation of virus. It should be noted that routine bacteriologic studies of scrapings gave entirely negative results in 2 of the 9 cases and that in the remaining 7 cases there was noted *Staphylococcus albus*, diphtheroids or gram positive bacilli (1 case). Also routine bacteriologic examinations of secretions from eyes of patients were essentially negative.

TABLE 3—Occupations and Original Diagnoses of Patients in the New York Study of Epidemic Keratoconjunctivitis

Employer	Type of Work	Number of Cases	Original Diagnosis

and isolation of such patients as soon as possible is strongly indicated. This is emphasized by the fact that in the present investigation direct definite transmission of the disease occurred in 3 instances: from a husband to his wife, from a girl to her fiancé and from a son-in-law to his father-in-law.

EXPERIMENTAL ASPECTS

The experimental phase of the investigation was divided into two parts. First, an attempt was made to repeat earlier work on the isolation of a virus.⁴ Second, additional serologic data were gathered to clarify the relationship between epidemic keratoconjunctivitis and the virus isolated previously.

Virus isolation experiments were carried out with conjunctival scrapings from 9 patients. The scrapings were obtained during the acute phase of the disease and were put into tube-tissue cultures (serum ultrafiltrate and embryonic mouse brain) which⁴ have been

Virus was isolated from the 2 specimens of scrapings which had contained no bacteria. In 1 of the 2 cases the 37 C series was negative (produced no symptoms when injected into mice) whereas the tissue culture kept at room temperature evoked symptoms in 2 of 6 animals within three days. Emulsion of the brains of these mice produced symptoms when injected into other mice, and the virus was maintained without difficulty. The virus is now in its fifteenth mouse passage and in its fourteenth tissue culture generation.

In the second case, both the 37 C and room temperature cultures gave positive results: the former bringing down 4 of 6 mice in two to six days and the latter producing symptoms in 3 of 6 mice within a similar period of time. In this instance also the virus was maintained without difficulty. It is now in its thirteenth mouse passage and in its seventh tissue culture generation.

In both instances in which virus was obtained all bacteriologic tests of brain emulsions and of tissue cultures were negative. The virus showed the same filtration activity (i. e. passed through membranes in

⁴ Simms, H. S. and Sanders, Murray. Use of Serum Ultrafiltrate in Tissue Cultures for Studying Deposition of Fat and for Propagation of Viruses. Arch. Path. 33: 619 (May) 1942.

the same range of average pore diameter) as the virus isolated previously in New York City from patients not connected with this group. The virus was also neutralized by serums from convalescent patients studied in both this and a previous investigation. These data strongly suggest the identity of the virus isolated in the present study with that observed originally.¹

The remaining attempts at isolation either were negative or resulted in transient symptoms in mice which could be maintained for only one, two or three mouse passages. The results of this phase of the experimental work were entirely consistent with previous experiments.

It was, of course, necessary to investigate further the specific nature of the isolated agent by testing with

* In all cases mortality rather than morbidity was used to determine the mouse titer. The highest dilution of virus which produced symptoms and death in the mice into which it was injected was considered the end point of virus activity.

† Patient 79 had bilateral involvement, the second eye becoming involved twenty days after the onset of the disease in the first eye.

Technic. Constant amounts of undiluted serum were mixed with equal amounts of serially diluted virus. The mixtures were held for one hour at 37 C and for four hours in the ice box and then injected intraperitoneally (0.1 cc) into unweaned mice.

convalescent serum. Serums were obtained from as many patients as possible. This could not always be done, however, and specimens were taken from only a relatively small number of patients, i. e. 19 individuals.

In 8 of the 19 cases studied we were able to obtain 2 serum specimens, 1 taken as soon as possible after the onset of the disease and the other taken seventeen to thirty-four days after the first. So far, 6 of these serums have been tested. In these 6 cases the development of specific antibodies has been clearly demonstrated. In 1 instance the first specimen when mixed with virus gave a titer approximating that of the control serum-virus mixture, but in the other cases an appreciable interval had elapsed between the onset of the disease and the time at which the first specimen was obtained, and neutralization varying from 10 to 100 neutralizing doses was therefore observed. The later specimens gave neutralization of from 1,000 to

10,000 doses, showing that a distinct increase in antibodies had occurred. These results are summarized in table 4. It will be noted that some of the patients seemed to respond much more rapidly than other patients, as measured by the number of neutralizing doses which could be demonstrated, but great care must be taken in interpreting the antibody responses, since the present group of patients is small and it is not possible to evaluate the effect of such individual variables as severity or duration of disease. The most important fact is that the first specimens contained one level of neutralizing antibodies, and later serum specimens showed an increase.

In the remaining 11 cases, in which only 1 serum specimen could be obtained the specimen was taken about one month after the onset of the disease and after the acute phase had passed. The serums showed neutralization varying from 100 to 10,000 mouse doses.

The technic in these experiments was similar to that described in a previous report, i. e., constant amounts of undiluted serum were mixed with equal amounts of serially diluted virus to give the final dilutions desired, these mixtures were kept one hour at 37 C and were then injected intraperitoneally (0.1 cc) into unweaned mice. In all cases mortality rather than morbidity was used to determine the mouse titer. The highest dilution which produced symptoms and death in the mice into which it was injected was considered the end point of virus activity.

The virus used was that isolated from E. L. (not included in this group of patients) in April 1942.

SUMMARY

1 Clinical, experimental and epidemiologic data have been obtained in 80 cases of epidemic keratoconjunctivitis.

2 The following features were found to be diagnostically significant in all cases in this study: hyperemia and swelling of the palpebral conjunctiva, congested and hyperemic bulbar conjunctiva, edema of the lids and occasional pseudomembranes on the conjunctiva of the lower lid. In addition, lymph node involvement and the absence of discharge were found to predominate.

3 Forty-two patients had corneal involvement. There has been no absorption of corneal opacities after a period of five months.

4 Of the 42 cases of corneal involvement 14 (33 1/3 per cent) showed impairment of vision varying from 5 to 15 per cent.

5 The relationship between the ocular disease and systemic symptoms was investigated. 49 patients (61.2 per cent) complained of headaches, 9 patients having severe headaches, 26 patients (32.5 per cent) complained of malaise.

6 In 3 cases severe systemic reactions occurred in the presence of a mild ocular disease. All patients with severe ocular involvement had systemic symptoms.

7 Fifty-seven patients (71.2 per cent) lost from one to eight weeks from work because of epidemic keratoconjunctivitis.

8 Epidemiologic data showed that there appeared to be individual predisposing factors present, but the nature of these factors is not fully understood. Of the 80 cases presented, 70 presented epidemic keratoconjunctivitis subsequent to ocular trauma or inflammation.

9 In two of nine attempts, direct implantation of cultures with conjunctival scrapings yielded a filtrable virus which proved to be apparently identical with that isolated previously

10 The virus which was isolated on these two occasions produced definite symptoms in mice. It was neutralized by convalescent serum from a patient who had suffered from epidemic keratoconjunctivitis and who was not associated with the present group of patients

11 Nineteen convalescent serums from patients in this group were tested. Neutralizing antibodies against the virus varied from 100 to 10,000 mouse doses. The virus used in the neutralization experiments was that isolated in an independent study of epidemic keratoconjunctivitis in New York City

12 In 6 of the 19 cases antibody development was demonstrated. Specimens of serum taken as soon as possible after the onset of the disease were compared with specimens taken seventeen to thirty-four days after the first specimen was obtained. In all cases there was a distinct increase in the titers of the second samples indicating a specific relationship between the virus and epidemic keratoconjunctivitis

RECOMMENDATIONS

Because epidemic keratoconjunctivitis is a disease apparently new to continental United States, and because little definite information is available concerning its mode of spread, precautions should be taken to keep it under control. On the basis of the data which have been presented, the following recommendations are made

1 Physicians should become familiar with the clinical picture of epidemic keratoconjunctivitis, so that an early diagnosis can be made

2 Meticulous cleanliness and disinfection of the hands of physicians and nurses who have come into contact with a case of epidemic keratoconjunctivitis is indicated

3 All instruments should be thoroughly sterilized, and individual droppers and glass rods should be used for each patient

4 All solutions which can be so treated should be periodically boiled

5 Strict isolation of patients with the disease should be effected as soon as possible

6 All contacts of the patients should be observed for early signs of the disease

Rabies in the United States—Rabies has a somewhat characteristic distribution throughout the United States. Human cases during the past ten years have averaged 57 annually. Two states, namely Texas and Tennessee, have averaged 51 to 6 cases yearly for ten years, twelve states have averaged 21 to 5 cases annually, whereas sixteen states have been entirely free and four states have had but 1 case during the past ten years. The number of cases in animals is not so readily determined but in general follows the same distribution. Thus, Texas and California have reported an average of more than 1,000 proved cases annually during the past five years, and Tennessee, Georgia, Alabama, Ohio, Indiana, Michigan and Illinois at least 400 to 800. On the other hand, ten states have reported an average of only 1 or less annually.—Webster, Leslie T. Rabies, New York, Macmillan Company, 1942

Clinical Notes, Suggestions and New Instruments

TREATMENT OF SEVERE DIABETIC COMA WITH 1,820 UNITS OF INSULIN

CHARLES CABELL BAILEY, M.D., BOSTON

My purpose in this report is to emphasize the need of large doses of insulin in cases of severe diabetic coma. This patient received 1,820 units in seven hours, which is the second largest dose used in a series of 536 consecutive diabetic comas treated in the Joslin service in the New England Deaconess Hospital since May 1923. The greatest quantity, 2,272 units in the twenty-four hours before recovery, was given to a man who had a diabetic coma during a phase of insulin resistance. Joslin,

Recovery from Diabetic Coma with 1,820 Units of Insulin Despite a Blood Sugar of 1,232 Mg and a Carbon Dioxide Combining Power of 7 Volumes per Cent

Time	Crystalline Insulin Units	Carbon Dioxide

Root, White and Marble¹ in treating 536 diabetic comas employed an average dose of about 200 units of insulin in the first two or three hours of treatment. The patient to be described received 1,450 units during his first three hours in the hospital

REPORT OF CASE

A man aged 23 with onset of diabetes in 1930 at the age of 11 years was admitted to the New England Deaconess Hospital at 8 30 p m Sept 10, 1942 completely unconscious in diabetic coma

Congenital nystagmus and slight congenital pes cavus were present. His first attack of diabetic coma occurred in 1935, five years after the onset of his diabetes, and he recovered with 270 units of insulin. His second diabetic coma occurred in 1936 and this time he was given 350 units of insulin. Also in 1936 a diabetic cataract was removed from his right eye. His third attack of diabetic coma was in 1939 when he had a gangrenous appendix. An operation was performed during the coma and he recovered with only 145 units of insulin. A right nephrectomy was done in July 1940 because of a large right functionless pyonephrotic kidney.

From the George F. Baker Clinic, New England Deaconess Hospital. Elliott P. Joslin, M.D., medical director.
1 Joslin, E. P., Root, H. F., White, Priscilla and Marble, Alexander. Diabetic Coma. J. A. M. A. 119: 1160 (Aug 8) 1942.

The present, or fourth, attack of diabetic coma apparently was brought on by disregard of his diet. For three days before admission he was troubled with polydipsia and polyuria, but his appetite remained good. He reported for work on the night shift at 11 p. m. on September 9, at which time he first noticed anorexia and extreme polydipsia. During the night he felt 'groggy,' and nausea began at 5 a. m. on September 10, the day of admission. He vomited first at 5:30 and felt quite ill. Deep breathing or air hunger developed on his way home from work at 8 o'clock. At 8:30 he tried to take his usual injection of 40 units of crystalline and 40 units of protamine zinc insulin, but he felt so 'groggy and sick' that he bent his needle and failed in the attempt. He then lay down on his bed and was found unconscious by his mother at 6:30 p. m., ten hours later. His local physician Dr. Joseph A. Dunn, saw him at 7 o'clock, diagnosed diabetic coma, recognized the seriousness of his condition and gave him 70 units of regular insulin. He was admitted to the Deaconess Hospital at 8:30, one and a half hours later.

On admission he was completely unconscious and almost moribund with feeble gasping respirations. At 28 minutes the deep breathing and air hunger which he later recalled having noticed earlier in the day having disappeared. He appeared in a definite state of shock with a blood pressure of 76 systolic and 40 diastolic, flushed face, very dry tongue and a strong odor of acetone on his breath. The rectal temperature was 92 F and the pulse 94. The skin was dry and cold. The bladder was distended almost to the umbilicus. The liver was palpable 2 cm. below the costal margin. The lungs were clear and the heart was normal in size. The eyeballs were so soft that the tension could not be measured by an ophthalmologist even twelve hours after entrance. Lipemia retinalis was looked for but not found.

Tests for blood sugar and the carbon dioxide combining power of the blood were taken, the patient was covered with several blankets, and four warm water bottles were placed near him one blanket thickness from the body. The urine on admission had already given a red Benedict test and 4 plus diacetic acid and in consequence 50 units of crystalline insulin had been immediately injected.

A preliminary blood sugar report at 8:50 p. m., twenty minutes after entrance, showed that the blood sugar was above 1,000 mg. per hundred cubic centimeters whereupon 100 units of crystalline insulin was given intravenously and another 100 units subcutaneously. By this time the final report was ready and showed that the blood sugar was actually 1,232 mg. and that the carbon dioxide combining power was 7 volumes per cent.

Huge doses of crystalline insulin appeared indicated and therefore within the first four hours he received 1,550 units, 600 of which was given intravenously, the latter because of his poor circulation and obviously poor chance for its quick absorption. By the end of five and a half hours of hospital treatment he had received 1,750 units of insulin to which should be added the 70 units given by his local physician one and a half hours before admission, making a grand total of 1,820 units of insulin in seven hours. No more insulin was administered for the next seventeen hours. The division of the insulin dose and blood sugar response are given in the accompanying table.

Other treatment during the first six hours of hospitalization consisted of isotonic solution of sodium chloride, 3,000 cc. intravenously and 2,000 cc. subcutaneously, four doses of caffeine with sodium benzoate, each 7½ grains (0.5 Gm.) one of which was by vein, gastric lavage with warm water and the removal of 400 cc. of dark fluid, and finally a cleansing enema.

At 10 o'clock, ninety minutes after admission, the pulse, which had previously been regular, became totally irregular, and an electrocardiogram showed auricular fibrillation. By midnight the pulse was again regular and normal. A later electrocardiogram was also normal.

As the patient's condition improved the feeble gasping respiration changed to the typical deep labored Kussmaul type, after which the Kussmaul breathing gradually disappeared. The temperature rose steadily to normal over a period of sixteen

hours. He began to respond three hours after admission by mumbling and was able to answer questions seven hours after entry, and one and a half hours later commenced taking sips of water, orange juice and ginger ale. By the next morning, September 11, ten and a half hours after entrance, the blood sugar was 218 mg. and the carbon dioxide combining power 21 volumes per cent.

The admission blood pressure of 76/40 almost disappeared shortly afterward, although it was never actually registered below 40 mm. of mercury systolic. This, however, gradually rose as his general condition improved.

The blood cholesterol of 406 mg. fell in the first ten and a half hours to 284 mg. A phenolsulfonphthalein renal test showed a 56 per cent excretion in two hours despite the fact that there was only one kidney. Twelve hours after admission the red blood cell count was 3,760,000, hemoglobin 11.9 Gm. and white blood cell count 6,800. The initial nonprotein nitrogen of 55 mg. per hundred cubic centimeters dropped to 33 mg. two days later. The blood acetone (combined acetone, diacetic acid and beta-hydroxybutyric acid) was 195 mg. An examination of the urine two days after recovery showed a specific gravity of 1.014, no albuminuria, and no casts, red blood cells or white blood cells.

The remainder of his hospital stay during which he received supplementary vitamins in addition to his diet was uneventful and he was discharged September 23, thirteen days after he entered on a diet of carbohydrate 190 Gm., protein 90 Gm. and fat 90 Gm. with crystalline insulin 14 and protamine zinc insulin 52 units. His case represents the seventy-second successive recovery from diabetic coma with a carbon dioxide combining power of 20 volumes per cent or below in this clinic, although now January 1 the total successive recoveries number seventy-five, no death having taken place since August 1940.

COMMENT

This case teaches again that diabetic coma is a deficiency state, the deficiency being insulin and that in deep coma of prolonged duration massive doses of insulin are of prime importance. Other supplementary measures such as artificial warmth, saline infusions, gastric lavage and enemata, while very helpful, take definitely a secondary place to adequate doses of insulin.

ACCIDENTAL AMPHETAMINE SULFATE POISONING

A. J. HERTZOG, M.D., A. E. KARLSTROM, M.D., AND
M. J. BECHTEL, M.D., MINNEAPOLIS

Amphetamine (benzedrine) sulfate in recent years has become a useful and widely used drug. Although the toxicity of this agent has been claimed to be slight it still may be the source of accidental poisoning. A number of cases have been reported in which nonfatal toxic symptoms resulted from large doses of the drug. Ehrlich, Lewis and Krimmblaur¹ refer to a man aged 67 who recovered after accidental ingestion of between 300 and 800 mg. (most likely 450 mg., i. e. 5 to 6 mg. per kilogram). He was seen on the second morning with an elevated blood pressure and he was very excited and apprehensive. His heart action was violent. Therapy consisted of soluble pentobarbital only. Apfelberg² reported that a psychoneurotic man remained in coma thirty-six hours after taking 140 mg. of amphetamine sulfate. This patient recovered. Anderson and Scott³ reported a case in which collapse, vomiting and heart block with an occasional extrasystole occurred after ingestion of only 30 mg. (0.4 mg. per kilogram). It would appear that the tolerance for the drug varies greatly. Nathan-

From St. Barnabas Hospital and the Department of Pathology of the University of Minnesota Medical School.

son⁴ observed that older persons seemed to tolerate more of the drug than young people.

The only fatal case that we are able to find reported in the literature is that of Smith⁵ in 1939. This was a 25 year old college student who suddenly collapsed and died during an examination. He had been in the habit of taking 5 mg of amphetamine sulfate thirty minutes before each examination. It was considered probable that he had taken 30 mg of the drug during the few days prior to his death. At autopsy no adequate anatomic explanation was found to account for his death other than dilatation of the right auricle of the heart and gastric and splanchnic dilatation. A sample of the gastric contents was reported to contain 0.25 mg of the drug. Some have questioned whether death in this instance was actually due to the small quantity of amphetamine sulfate that the victim had taken. The fact that he had been in the habit of using the drug would exclude an idiosyncrasy.

REPORT OF CASE

A girl aged 12 months had always enjoyed good health. On the morning of Aug. 30, 1942 she was playing on the floor of the bedroom of her home with her 2 year old sister. The older child apparently climbed on a chair while alone and took from the medicine chest a box of amphetamine sulfate tablets and a bottle of ferrous sulfate tablets. It is believed that the sister then gave the younger child the tablets. Shortly before 8:30 a. m. the younger child was found on the floor in a state of collapse. She was very pale. There were 12 amphetamine sulfate tablets and a bottle of ferrous sulfate tablets scattered on the floor. The prescription for the amphetamine sulfate was easily identified. Thirty tablets of 10 mg each had been prescribed for an older relative as a nerve tonic. It was believed that 16 tablets had remained in the box before the accident and 12 tablets were found on the floor. Hence it was thought that the child took a minimum of 4 tablets, or 40 mg. However, the family was not very definite as to the number of tablets she had taken and it is quite possible that more than the amount stated had been taken by the child. The child was thought also to have taken an uncounted number of ferrous sulfate tablets of 3 grains (0.2 Gm.) each. The child was brought to St. Barnabas Hospital immediately. On admittance at 9:30 she was drowsy, cyanotic and semicomatose. Shortly after admittance she vomited brownish material. Gastric lavage revealed large quantities of brown colored material. The stomach was washed with plain water until the washings became clear. At one time during this procedure the pulse became feeble and undetectable. Respirations ceased temporarily but were reestablished by artificial respiration and carbon dioxide. The pulse remained rapid and weak. Erythematous blotches appeared over the skin of the extremities. Mucus collected in her throat. At 4:15 a. m. on August 31 extreme dilatation of her pupils was noted. Respirations became more shallow and she died at 5:05 in spite of artificial respiration approximately nineteen hours and thirty minutes after admission.

Autopsy was performed three hours and ten minutes after death. The body was 79 cm long and weighed 25 pounds (11.3 Kg.). The pupils were widely dilated and measured 7 mm. A number of reddish blotches of the skin on the anterior surfaces of the body was noted. The peritoneal and pleural cavities appeared normal. The heart weighed 45 Gm and showed no abnormalities. The right lung weighed 100 Gm and the left 65 Gm. They were a mottled hemorrhagic color and showed generalized edema. The spleen weighed 30 Gm. It showed no abnormalities. A state of contraction of the organ was not demonstrated. The liver weighed 310 Gm and grossly appeared normal. The mucosa of the esophagus was normal. The entire wall of the stomach including the serosa had a dark hemorrhagic color. The stomach contained approx-

imately 300 cc of greenish gray fluid. The mucosa was intact and had a grayish black color. The gastric contents did not have a characteristic odor. The duodenum and first portion of the jejunum showed slight discoloration of the mucosa. The mucosa of the remaining small bowel, colon and rectum appeared normal. The small bowel contained fluid similar to that found in the stomach. The pancreas appeared normal. The adrenals, especially the right showed a diffuse hemorrhagic discoloration. The kidneys weighed 40 Gm and 38 Gm respectively and showed nothing of note. The thymus weighed 14 Gm. The remaining examination revealed no abnormalities. The lumbar spinal cord appeared normal. The bone marrow of the sternum was red. Normal postmortem blood clots were present. Examination of the brain was not permitted.

The only significant findings microscopically were in the lungs, stomach and adrenals. Many of the alveoli of the lungs contained coagulated serum and red blood cells. The mucosa of the stomach was intact. The remaining gastric wall showed a recent diffuse hemorrhage with many red blood cells present. A potassium ferricyanide stain showed a large amount of iron pigment deposited in the mucosa of the stomach. Both adrenals showed a recent hemorrhage located for the most part in the region of the medulla. A postmortem blood count showed 68 per cent lymphocytes, 29 per cent polymorphonuclear neutrophils, 2 per cent eosinophils and 1 per cent monocytes. An imprint of the bone marrow from the sternum showed a normal appearing marrow with active hemopoiesis. Megalokaryocytes were present. The anatomic diagnosis was recent hemorrhage in the gastric wall and adrenals and edema of the lungs. Death was attributed to amphetamine sulfate poisoning.

COMMENT

The sudden collapse followed by coma and death of a healthy 1 year old child following the accidental ingestion of amphetamine sulfate and ferrous sulfate together with the autopsy findings, established poisoning as the cause of death. Ferrous sulfate can be eliminated as the cause since this iron preparation is relatively nontoxic. Amphetamine sulfate is a powerful sympathetic stimulant closely related chemically and physiologically to epinephrine. Unlike epinephrine amphetamine sulfate is destroyed very slowly by the body and its effects are more lasting. Ehrlich, Lewy and Krumbhaar¹ found no specific anatomic changes in animals dying of lethal doses of amphetamine sulfate. In a wide variety of animals they reported dilatation of the heart, congestion of the liver and kidneys, either congestion or contraction of the spleen, the presence of air in the stomach and intestines and in some animals subpleural and pericardial hemorrhages as well as well defined and sharply demarcated areas of constriction of the small intestine. A few of the animals showed necrosis of the liver and spleen. In monkeys the findings in the central nervous system were venous stasis and perivenous hemorrhages in the meninges and white matter of the hemispheres and cerebellum. Toxic degeneration of some of the nerve cells in these regions were also noted. The authors found the minimum lethal dose of the drug to vary considerably with the age and species of the animal. Young monkeys were the most susceptible in which 5 mg per kilogram was a lethal dose while an adult monkey required from 20 to 25 mg per kilogram. It appears that our patient had received 35 mg per kilogram of body weight. The family could not be very definite as to the exact number of tablets taken however and it is possible that she received considerably more than this amount. The hemorrhage in the regions of the medulla of the adrenals found at autopsy suggests a possible relation with the sympathicotrophic action of the drug. At present there is no specific antidote for amphetamine sulfate poisoning.

SUMMARY

Sudden collapse with coma and death occurred in a 1 year old child following the accidental taking of ferrous sulfate and amphetamine sulfate. Death is considered to have been the result of amphetamine sulfate poisoning.

Council on Foods and Nutrition

THE COUNCIL ON FOODS AND NUTRITION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
FRANKLIN C. BING, Secretary

VEGETABLE JUICE COCKTAILS

The commercial production of canned tomato juice is a relatively new and now important industry. At one time little attention was given to the vitamin C content of the finished product. Then, largely as a result of investigations conducted under the auspices of the National Canners Association, it was learned that considerable destruction of vitamin C may occur unless precautions are taken to eliminate air in the processing. This can be done by conducting the canning operations in an atmosphere of steam. Other improvements in technological procedure were developed and today commercially canned tomato juice can be expected confidently to provide the full vitamin C

Vitamin C in Mixed Vegetable Juices and in Ordinary Canned Tomato Juice

content of the freshly expressed juice. Losses in the can likewise appear to be small, although this factor needs further study. There is evidence that the vitamin C is retained better in tinned containers than in glass.

With the development of canned tomato juice as an important food item there has been witnessed also the more recent production of what have been called tomato juice or vegetable juice cocktails. One such preparation has been accepted by the Council for a number of years, it consists of ordinary canned tomato juice with a dash of tabasco sauce for flavoring purposes. Of late, however, there have been developed juices in which tomato juice may represent less than 60 per cent of the total volume. The question arises: How does this manipulation of tomato juice affect the nutritional quality of the products?

At its meeting in March 1942 the Council discussed the available evidence on this problem and decided¹ not to approve of mixed vegetable juices of inferior nutritive value. The evidence then on hand showed clearly that these so-called vegetable juice cocktails have less vitamin C than ordinary tomato juice.

There is an additional health aspect to the vegetable juices, or suspensions of finely minced vegetable material, especially those which are made by so-called health food stores for dis-

persing to the public. Tomato juice, like the citrus fruit juices, is quite acid in reaction and therefore requires less heat treatment to render it safe from spoilage organisms or pathogenic bacteria than is necessary in the processing of less acid juices. Carrot juice, celery juice and the like are less acid than tomato juice and their addition to tomato juice reduces the hydrogen ion concentration. The mixed juices therefore may require quite different processing times and temperatures. The recent tracing in California of 2 cases of typhoid to contaminated carrot juice, improperly pasteurized, is an example of a hazard that all too frequently is overlooked by the amateur or inexperienced food dispenser.²

Correspondence with firms has indicated that sometimes little attention has been given either to the sanitary or to the nutritive aspects of these mixed vegetable juices. For that reason samples of representative products were purchased on the open market. Also samples of tomato juice were obtained for comparative purposes. These specimens were examined for their vitamin C content and hydrogen ion concentrations in the A. M. A. Chemical Laboratory by Dr. Albert E. Sidwell and Dr. George O. Sharp. The data are provided in the accompanying table. The pH was determined by the glass electrode method. The ascorbic acid concentration was determined by titration with 2,6-dichlorophenolindophenol according to a modification of the method of Bessey and King³ as described by Thornton.⁴

The figures show that the average ascorbic acid content is less than that of undiluted tomato juice. The pH in general is slightly less acid, so that no special problem would be presented in the proper processing of these particular products. The values for the ascorbic acid content of canned tomato juice in this series average 168 mg. to each hundred cubic centimeters. In some earlier tests performed for the Council by Dr. E. M. Bailey of the Connecticut Agricultural Experiment Station the average ascorbic acid content of seventeen brands of tomato juice was 180 mg. to each hundred cubic centimeters. Although some of the better mixed juices approach the vitamin C content of the poorer samples of tomato juice, the average of the samples examined and reported herein is about half the value of tomato juice.

No determinations were made of the carotene content of these products. It would appear, from the nature of the manufacturing processes that the vitamin A value of the mixed juices likewise is less than that of undiluted tomato juice.

The advertising of the mixed vegetable juices is apt to be misleading, because of the impression that the products contain the food values of each ingredient. The uninformed reader no doubt gains the erroneous impression that all the nourishment of celery, parsley, carrots, spinach, lettuce, endive, watercress and perhaps other vegetables is in a product. Instead of being superior products, the present report shows that the mixed vegetable juices are likely to be inferior in nutritive value to ordinary tomato juice.

It is of interest that the War Production Board in its original M-81 order early in 1942 restricted the production of canned mixed vegetable juices containing less than 70 per cent tomato juice, but apparently this order later was rescinded. More recently the War Production Board again has severely restricted the production of these products during 1943. A factor that may need consideration in evaluating the products from the point of view of essentiality in wartime is the question of what becomes of the solid part of the vegetable, the juice of which is used to dilute the tomato juice. Is this material with its unextracted food values discarded? What is the cost of the products as compared to the cost of better known relatively standard items? The answers to such questions no doubt will help in the complete evaluation of the significance of the various mixed vegetable juices that have been developed, but such considerations are not within the purview of the Council.

⁵ The Vitamin C Content of Commercially Canned Tomato Juice and Other Fruit Juices as Determined by Chemical Titration, J. A. M. A. **110**, 650 (Feb. 26) 1938.

In view of the foregoing facts the Council reaffirms its decision not to approve of the production of mixed vegetable juices of inferior nutritive value. The Council also voted to authorize publication of the present report with a view to providing some of the considerations which have led to the present decision.

Council on Industrial Health

MEDICAL SERVICE IN INDUSTRY

THE COUNCIL ON INDUSTRIAL HEALTH HAS APPROVED THIS ARTICLE AS THE SIXTH IN A SERIES ON MEDICAL SERVICE IN INDUSTRY

C. M. PETERSON, M.D., Secretary

AN INDUSTRIAL HEALTH PROGRAM FOR A COUNTY MEDICAL SOCIETY

At the request of the War Participation Committee of the American Medical Association, the Council on Industrial Health has prepared a program for improved county medical society organization to enable physicians to contribute more directly to industrial health activity in small plants. Local circumstances should modify these recommendations as needed.

ORGANIZATION OF THE COMMITTEE

Every medical society in a county having sufficient industrial concentration to justify it, should organize a committee on industrial health. There should be representation on the committee from (1) private practice, (2) industrial practice and (3) the local health department. These are the essential professional groups needed to supply an adequate health service to industry in any community.

It is desirable also that an executive officer of the county medical society should be a member of the committee.

OBJECTIVES OF THE COMMITTEE

The committee should understand the components of an adequate industrial health service and be prepared to adjust them to existing local medical and public health facilities and to patterns of community medical practice.

The essentials of an industrial health service are:

1 A competent physician who takes genuine interest in applying the principles of preventive medicine and hygiene to employed groups and who is willing to devote regular hours to such service in the working environment.

2 Industrial nurses with proper preparation, acting under the physician's immediate supervision or under standing orders developed by him or by the committee on industrial health of the county medical society.

3 Industrial hygiene service directed at improvement of working environment and control of all unhealthful exposures, to be provided by physicians and others with guidance and assistance from the specialized personnel in state and local bureaus of industrial hygiene.

4 A health program which should include:

(a) Prompt and dependable first aid, emergency and subsequent medical and surgical care for all industrially induced disability.

(b) Health conservation of employees through physical supervision and health education.

(c) Close correlation with family physicians and other community health agencies for early and proper management of nonoccupational sickness and injury.

(d) Good records of all causes of absence from work as a guide to the establishment of preventive measures.

COMMITTEE ACTIVITY

The following recommendations will be supplemented from time to time by instructions made up from reports issued by the Council on Industrial Health and from other sources. The material will reach the committees through industrial health bulletins, medical journals, direct correspondence and the Council's field activities.

1 The committee in the county society should request instruction from the committee on industrial health in the state medical association and from the state division of industrial hygiene. Preferably, a preliminary conference should be held with representatives of these two agencies to establish:

(a) The lines of relationship and responsibility already existing between government, industry, labor and the medical profession.

(b) The principal industrial health problems of the community as a basis for remedial action.

(c) The proper organization and employment of local medical and health facilities.

(d) Supplementary services which can be called on from sources outside the community itself.

The needs of small industry should be particularly stressed.

2 The names of all physicians now serving or willing to serve in industry should be determined. These physicians should be invited to attend a meeting at which the results of the preliminary conference just described can be reported and general details of the program presented for discussion and adoption.

3 Conferences should be held with other essential professional groups, particularly industrial or public health nurses and industrial hygienists, in order that dependable arrangements for services provided by these groups may be made.

4 The county medical society committee should then request a conference with the executives or a representative committee of the local manufacturers' association, chamber of commerce or both to describe the program and to determine how the medical profession and the local health department can accelerate and improve production through appropriate health activity. Specifically, the following items should be discussed:

(a) The essentials of industrial health service as outlined.

(b) The health and economic benefits of such a service.

(c) Methods of supplying this service.

(d) Probable cost.

The committee of the manufacturers' association can well be asked to act permanently as adviser to the county medical society committee.

5 Active cooperation should be secured from local labor organizations both in respect to the conduct of medical services in the plant and to establish a program of health education in the community. Health education should emphasize particularly nonoccupational factors which are of importance to the health of workers—nutrition, housing, proper use of leisure time, recreation and other related activities. The committee representative of local labor organizations should be requested to assume a considerable share of responsibility for the health educational aspects of the program and should regularly act in an advisory capacity to the committee on industrial health of the medical society.

6 The next procedure should be an open meeting conducted jointly by the county medical society and the local manufacturers' organization or chamber of commerce, to which employers, physicians, other professional agencies, representatives of labor and, in fact, the community at large can be invited. This meeting will provide means for promoting the program widely throughout local industry.

7 Following preliminary organization, the activities of the county medical society's committee on industrial health will fall mainly under four major headings:

(a) Investigation of local causes of lost time in industry as a basis for necessary remedial service.

(b) Coordination of community industrial health facilities.

(c) Frequent education of the public about the benefits of an industrial health program.

(d) Continuous education of the medical profession as a means for elevating standards of industrial health service.

In all other ways the committee should exercise that degree of initiative and leadership which will properly represent medical responsibilities and opportunities in this important field.

CONTINUOUS CAUDAL ANALGESIA IN OBSTETRICS—A METHOD FOR SAFE, PAINLESS CHILDBIRTH

Elsewhere in this issue appear two papers by Hingson and Edwards¹ and by Gready and Hesselstine² dealing with a method called continuous caudal analgesia, used in obstetrics for the relief of pain during childbirth. The method, which is a natural outgrowth of the development of local, spinal and caudal anesthesia was first used in obstetrics in the U. S. Public Health Service Marine Hospital at Stapleton on Staten Island, New York, on Jan 6 1942. Since that time the method has been tried in some nineteen clinics associated with medical schools and well established hospitals. Altogether some 589 women have been delivered of babies by this method without maternal mortality and with but 3 instances in which infants died—these without reference to the method of analgesia that was employed.

As will be observed by a careful reading of the articles, the technique is one which demands the competent art of the specially trained anesthetist or surgeon and the practice of a high order of obstetric science. It is not a method for indiscriminate use in the home or by those who have not been especially trained in its technique or in a realization of conditions which might contraindicate its use. These considerations are especially emphasized in both the manuscripts which are published. Indeed, Drs Hingson and Edwards, before undertaking their technique, dissected many cadavers to study at first hand the anatomy of the region concerned. They have continued their study toward improvement of the method by modifications of the apparatus concerned, the solutions used and the methods of use.

The relief of pain in childbirth has been one of the long sought goals of the medical profession. In developing their technique Drs Hingson and Edwards traveled

frequently to leading institutions of medical education and to lying-in hospitals in order to train men working in these fields in the technique that they themselves had elaborated. The significance of the observation is such that the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION considered it desirable to assemble promptly the opinions of some of those who have had opportunity to test the method under controlled conditions in hospitals. The following is a statement by Dr Norris W Vauv, professor of obstetrics at Jefferson Medical College and obstetrician and gynecologist-in-chief at the Philadelphia Lying-In Hospital.

Our experience at the Philadelphia Lying-In Hospital with continuous caudal analgesia since July has been highly satisfactory. It is a 100 per cent effective analgesia and is not dangerous if properly administered using the technique outlined by Drs Hingson and Edwards. It needs constant supervision by some one trained in the technique.

There are a few contraindications to its use, chief of which is placenta previa.

The labor is definitely shortened. Cervical dilatation is more rapid. Postpartum blood loss is less. Primary respiration in the infant is established promptly. Involution of the uterus is hastened. This form of analgesia does not inhibit or delay lactation. Bladder function is not disturbed. There is no lower extremity paralysis.

In all surgical procedures the tissues heal rapidly. Our clinic is using this method cautiously under the supervision of an anesthetist trained in the administration of spinal anesthesia. Our time has been limited in the use of this method, but our results so far show that it is the best method yet devised for the relief of pain in labor.

Another obstetrician who had opportunity to test the method for a considerable period is Dr Francis R Irving, associate professor of clinical obstetrics at Syracuse (N. Y.) University College of Medicine. He states:

Dilatation occurs rapidly soon after administration of the analgesia. We find that the needles are troublesome regardless of flexibility and utilize a catheter instead of the needle. We have delivered 85 women since October 10 without failures. There is no question that it is perfect painless childbirth without deleterious effect on mother or child.

The use of this method shortens labor and relieves the soft parts. We have had considerable experience with scopolamine, the barbiturates and paraldehyde.

As a complication the physician should watch particularly the fetal heart. The knee elbow position of the mother may cause pressure on the cord and thus affect the fetal heart. This has no bearing on the technique but is a danger which should be observed. The procedure may be accomplished with the patient lying on her side, but that is a technical difficulty which is important as far as the baby is concerned. If the obstetrician will realize that the position of the mother may affect the fetal heart the method would seem to be the best word in obstetric analgesia.

Dr John S Lundy, head of the Department of Anesthesia in the Mayo Clinic, Rochester, Minn., says:

We have used continuous caudal analgesia about fifty times and I think it is fine. It has also been used successfully in Brook General Hospital, Fort Sam Houston, Texas, Walter Reed Hospital, Washington D. C., and many other places.

The time since the introduction of this method has been exceedingly brief. Nevertheless the experience accumulated seems to be sufficient to warrant the belief

¹ Hingson Robert A. and Edwards Waldo B. Continuous Caudal Analgesia in Obstetrics this issue p. 225.

² Gready Thomas G. Jr. and Hesselstine H. Close Continuous Caudal Anesthesia in Obstetrics this issue p. 229.

that it constitutes a real advance in securing relief of pain for mothers during childbirth. As with all other advances made in modern medical science, those who are especially trained in the method and who learn to avoid its use in cases in which the contraindications are clear are likely to be most successful in its employment. As is emphasized by all who have discussed the subject in this issue of *THE JOURNAL*, including Drs Hingson and Edwards, Gready and Hesseltine, Vaux, Irving and Lundy, the method should be used only in hospitals in which there are available the services of persons trained in the administration of the analgesia and obstetricians competent to conduct a delivery with the scientific considerations and finesse associated with the special practice of the obstetric art.

With continued use of this method, still further improvements will no doubt result. Drs Hingson and Edwards are physicians commissioned in the United States Public Health Service. On them largely will fall the burden of educating other physicians in the principles of the technique and in the conditions which should govern its use. Already they have given frequently of themselves of their time and of their efforts in traveling to more than nineteen medical schools and hospitals, in which they have stayed for periods sufficiently long to instruct men already well trained in anesthesia and in obstetrics. From all these areas come reports such as those here cited which are more than encouraging as to the objective that has been attained. The extension of this advance in medical and obstetric science to physicians and to prospective mothers places another burden on those agencies in the United States which are cooperating in extending graduate education to the medical profession.

CONTROL OF AIR BORNE INFECTION

Working at Harvard University, William F and Mildred W Wells¹ invented an apparatus and developed a technique which made it possible to explore the air for micro-organisms in controlled atmospheres. Liquid suspensions of micro-organisms could be atomized into a tank and their presence demonstrated quantitatively by the air centrifuge. These researches established that transmission of infection through the air may take one of two forms, depending on the size of the infected droplet. The more obvious form recognized by Flugge is droplet infection proper. It applies to droplets larger than 0.1 mm in diameter, which are rapidly removed from the air by gravity before they can dry and within a short distance from the source. The second form may be called air borne infection and deals with the dried residue of infected droplets or droplet nuclei, derived directly from droplets less than

0.1 mm, depending primarily on air for the buoyancy that keeps them suspended for longer times and carries them longer distances. The Wellses² also investigated the bactericidal effect of ultraviolet radiation on micro-organisms suspended in air and proved it to be of a higher order of magnitude than humidity, ozone or commercial germicides.

With Wilder the Wellses³ carried out a four years study in the Germantown Friends' School and a one year study in the Swarthmore public schools. They were able to report that, as the result of ultraviolet irradiation there has been no epidemic spread of contagion among the highly susceptible groups of children of primary schools, although epidemic spread has occurred among less susceptible groups of older children in the departments of schools whose atmospheres were not irradiated. The experiment supports the hypothesis that epidemic contagion is spread through the medium of confined atmospheres and that it can be prevented by radiant disinfection of air. Deryl Hart and his co-workers established that air is an important source of contamination in every operative wound and that sterilization of the air in the operating room can be accomplished by bactericidal irradiation.⁴ Del Mundo and McKhann⁵ reported that the hospital infection rate during the winter of 1939-1940 in a control ward of the Infants' Hospital of Boston was 12.5 per cent, but in a ward in which the conditions were entirely comparable except that each cubicle was protected across the front and across the top by ultraviolet radiation the cross infection rate was 2.7 per cent. Sommer and Stokes⁶ found that ultraviolet radiation was effective in reducing the number of air borne organisms in a hospital ward.

Recently Henle and his associates⁷ prevented air borne infection in white mice exposed in a large hospital ward subdivided into sixteen separate cubicles by using ultraviolet radiation or sprays of propylene glycol. Groups of animals were placed in some of the locations, while cultures of the hemolytic streptococcus of Lancefield's group C or of the virus of influenza A were atomized in one of the cubicles. Both organisms spread rapidly throughout the air of the ward. Ultraviolet radiation and propylene glycol vapor were com-

pared in their effectiveness as disinfectants of the air. With heavy concentrations of air borne streptococci (more than 3,000 cells per cubic foot of air) most of the control mice died from streptococcic pneumonia and septicemia, while propylene glycol vapor protected them completely and ultraviolet radiation failed to prevent death only in the cubicle containing the atomizer. With low concentrations of the streptococcus (200 to 500 organisms per cubic foot of air) all mice survived and cultures taken from the lungs on the eighth or tenth day failed to reveal the streptococcus. However, it could be shown in other experiments that a carrier state had been induced in the animals exposed under control conditions and not in those protected by ultraviolet barriers. This was demonstrated by inoculation of the virus of influenza A eight to ten days after exposure to the air borne streptococcus. All mice died from influenza, but only those belonging to the control group now showed hemolytic streptococci in cultures taken from the lungs. Ultraviolet radiation and propylene glycol vapor were similarly effective in preventing the air borne infection with the virus of influenza A. These results indicate that both ultraviolet radiation and propylene glycol vapor are effective disinfectants of the air. Their application will depend on the individual problems and the location to be disinfected.

SCIENTIFIC INFORMATION FOR MEDICAL OFFICERS

Two projects now well under way, recently developed, are additional assurance to physicians associated with the armed forces of opportunity to keep themselves abreast of advances in medical science. By cooperation of the editorial staff of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* with the Committee on Information of the Division of Medical Sciences of the National Research Council and the Divisions of Publications of the United States Army and Navy Medical Departments and the United States Public Health Service, a letter is being prepared every two weeks, which is distributed to every officer in these services. Such letters are sent by air mail or by V-letter to various camps and hospitals and are there mimeographed for distribution to the individual officers. In some instances, copy is sent directly to an individual officer. The letters consist of from four to six pages of brief abstracts of articles of significance appearing in the current medical literature.

By special arrangement also E. R. Squibb and Sons has planned to distribute to officers in the armed forces a publication called *Medical Journal Abstracts*, prepared by the library staff of this company. Copies of this periodical are sent to each station, camp, hospital or post in care of the chief medical officer or the chief

surgical officer and then distributed by him to the medical officers in his group. The company offers to send *Medical Journal Abstracts* on receipt of a correct APO address also to medical officers overseas, subject, of course, to decisions of governmental authorities in charge of postal regulations.

Certainly these attempts to aid physicians in the armed forces to keep abreast of advances in medical science can result only in improvement in medical service to the men for whose health and medical care they are responsible.

Current Comment

THE OPINION OF THE SUPREME COURT

In the text of the opinion of the Supreme Court, published elsewhere in this issue (page 267), attention is called to the following paragraphs:

Paragraph 6—"First Much argument has been addressed to the question whether a physician's practice of his profession constitutes trade under Section 3 of the Sherman Act. In the light of what we shall say with respect to the charge laid in the indictment, we need not consider or decide this question."

Paragraph 7—"Group Health is a membership corporation engaged in business or trade. Its corporate activity is the consummation of the cooperative effort of its members to obtain for themselves and their families medical service and hospitalization on a risk-sharing prepayment basis. The corporation collects its funds from members. With these funds physicians are employed and hospitalization procured on behalf of members and their dependents. The fact that it is cooperative, and procures service and facilities on behalf of its members only, does not remove its activities from the sphere of business."

Paragraph 28—"We need add but a word as to the sufficiency of the proof to sustain the charge. The petitioners in effect challenge the sufficiency, in law, of the indictment. They hardly suggest that if the pleading charges an offense there was no substantial evidence of the commission of the offense. But, however the argument is viewed, we agree with the courts below that the case was one for submission to a jury. No purpose would be served by detailed discussion of the proofs."

Paragraph 29—"Third. We hold that the dispute between petitioners and their members, and Group Health and its members, was not one concerning terms and conditions of employment within the Clayton and the Norris-La Guardia Acts."

Paragraph 37—"In truth, the petitioners represented physicians who desired that they and all others should practice independently on a fee for service basis where whatever arrangement for payment each had was a matter that lay between him and his patient in each individual case of service or treatment. The petitioners were not an association of employees in any proper sense of the term. They were an association of individual practitioners each exercising his calling as an independent unit. These independent physicians, and the two petitioning associations which represent them, were interested solely in preventing the operation of a business conducted in corporate form by Group Health."

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Mobilization of manpower necessitates many unusual readjustments. The mobilization of the medical profession for service to the armed forces and to civilians and the maintenance of production of physicians have been fraught with many difficulties. The medical schools of the country have voluntarily reduced the period required for the curriculum of the medical school from four to three years. The required pre-medical college course has been reduced to two academic years. Now the War Manpower Commission and other federal agencies have formulated a coordinated program looking to the satisfactory training of an adequate number of physicians to meet both the military and the civilian needs. Many of the details in regard to this program have not yet been clarified. The seriousness of the many problems involved, affecting as they do the lives of thousands of young men as well as the efficient conduct of many of the colleges of arts and all of the medical schools of the country, emphasizes the importance of the Annual Congress on Medical Education and Licensure to be held at the Palmer House in Chicago on February 15 and 16. The program appears in this issue of *THE JOURNAL* on page 269. One of the greatest problems involved in the mobilization of the medical profession is the meeting of changing civilian and industrial needs. This calls for the relocation of many physicians and the consequent adjustment of state licensure regulations. The program, including as it does addresses by President Elliott, chief of the Professional and Technical Employment and Training Division of the War Manpower Commission, General Dalton of the U S Army, representatives of the Office of Procurement and Assignment and the Surgeon Generals of the U S Army, the U S Navy, and the U S Public Health Service, should go far toward clarifying the details of the various programs involving the whole field of medicine in the war.

MALARIAL HEMAGGLUTINATION

An interesting contribution to the pathology of malaria is contained in a study of intravascular hemagglutination in birds infected with *Plasmodium cathemerium*, currently reported by Lack¹ of the University of Tennessee. Using the Knisely quartz rod microilluminator, the investigator studied the histopathology of the circulation in the wing web of normal and experimentally infected canaries. A drop of liquid petrolatum placed on the epithelium facilitated visualization at a magnification of 96 diameters. All experimentally infected birds developed parasites in the blood stream with counts up to 67 per cent, from which all but one bird died. As the parasite count began to rise there was an initial loss of "streamlining" in the peripheral circulations accompanied by transient sticking of leukocytes to the endothelial lining of the venules plus evidence of plasma leakage. As the count increased the white cells became adherent to the endothelium in

ever increasing numbers, accompanied by the formation of sticky clumps of red cells which retarded the rate of blood flow in many areas. In the subsequent twenty-four to forty-eight hours came progressive intravascular clumping. The clumps were now fairly firm, could withstand intravascular stress and occasionally appeared in the arterioles. Plasma viscosity was apparently increased. The clumps were originally formed only by parasitized cells but later included both infected and normal erythrocytes. The final stage was a "pastelike" blood flow followed by death of the bird within a few hours. Intravascular agglutination had previously been described in experimental malarial monkeys by Knisely and his co-workers of the University of Chicago. The phenomenon presumably occurs in man.

FATAL ACCIDENTS TO INFANTS IN WARTIME

According to a recent issue of the Statistical Bulletin of the Metropolitan Life Insurance Company¹ a rising birth rate such as has been experienced during the last few years is inevitably accompanied by a proportionate increase in the accidental deaths in earliest childhood, especially in view of the present haphazard attitude toward child safety. It may therefore be anticipated that for the year 1942, and probably also for 1943, the figures on the number of children under 1 year of age who die of accidental injuries will be well above the average of the last ten years. Experience has shown that, of every thousand born, 1 will die in the first year of life as the result of an accident. If this ratio persists, 2,600 children under 1 year of age will be found to have been accidentally killed in 1942. The number, moreover, may be as high as 3,000 if, as is not unlikely, there was an actual increase in the accidental death rate during the year. Among the most important factors which influence this death rate, as pointed out in the report, are early maternal absences and the attempt to keep infants warm by heavy covers—the latter a factor of special importance to parents living in homes subject to fuel oil rationing. Indeed, the greatest hazard encountered by infants is that due to smothering. The parent who covers the child with more or heavier blankets to offset the decrease in the amount of heat in the home this winter should make sure that the bed clothing is arranged so that the child cannot be suffocated. Fatalities in infants frequently occur also from foreign bodies lodged in the air passages, particularly aspirated vomitus, inhaling of food and the swallowing of safety pins, marbles, thumb tacks and other objects. Hot water bottles left in the crib to keep it warm should be well covered and tested to see that they are not so hot as to burn the baby. Other causes of accidents are hot liquids in pots, pans and cups left within reach of babies, poisons and drugs left carelessly about, stoves or other hot objects against which the child may fall, and falls out of cribs, beds and windows and down stairs.

¹ Statistical Bulletin Metropolitan Life Insurance Company 23:3 (Nov.) 1942.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

THE ARMY FLIGHT SURGEON

The flight surgeon today, as described by Brig Gen David N W Grant, U S air surgeon Army Air Forces in the *Army and Navy Journal* of January 2 is an integral part of the Army Air Forces, that is, of air research and development of every combat unit of every air evacuation unit and of the paratroopers. The flight surgeon plays a major role in the development and maintenance of *esprit de corps* and morale among the personnel of the army air forces. He has developed methods for selecting from the youth of America those whose aptitude for flying is greatest. He preserves and conserves manpower of the air forces at maximum efficiency through the supervision of a carefully studied and specially constituted application of preventive medicine. He is responsible for the restoration of combat casualties to active health.

General Grant continues. The supercharged high powered motor which enables aircraft to fly at altitudes of 40,000 feet has introduced the complex problem of hypoxia. Above 10,000 feet there is insufficient oxygen for normal physiologic requirements. Above 20,000-25,000 feet life cannot be maintained without the use of accessory oxygen equipment. At 40,000 feet it is impossible for the human being even when breathing pure oxygen to live without using pressurized breathing equipment. Thanks to the development of the oxygen mask and regulators our air combat forces are now operating routinely and safely in the vicinity of 35,000 feet.

Motion sickness referred to in the air forces as "air sickness" has been a serious problem. The aviation cadet who repeatedly

becomes airsick must be eliminated. Air borne troops are unable to fight after parachuting to earth if they are airsick. Prevention and control of airsickness are subjects of extensive research. Selection tests are now being developed so that potentially airsick individuals will not be accepted for training. The use of special ear tests and the correlations of swing sickness with airsickness have revealed valuable facts about the inner ear which may help in the solution of this problem.

The intensity of aircraft motor noise the loudest known to man has been a difficult problem. Even the loudest thunder cannot be heard while flying. Noise of this magnitude produces a definite though limited impairment in a part of the range of auditory perception. Owing to the shape of the ear and ear canal it has not been possible to design an ear phone which will satisfactorily exclude motor and propeller noise. The ratio of motor noise intensity to signal intensity has not yet been sufficiently reduced to permit ideal radio communication.

Air evacuation of wounded soldiers from the front lines to large surgical hospitals in the rear is one of the great advances of medical care in this war. The speed and ease of air evacuation establish a higher level of morale among troops. The flight surgeon is therefore charged with many responsibilities. He practices a highly specialized form of applied preventive medicine and assists in the development of equipment to increase the pilot's physiologic performance. He must briefly be a good doctor, counselor and friend and in the personnel under his jurisdiction become sick or wounded in combat he sees to it that they receive adequate and prompt attention.

AVIATION MEDICAL EXAMINERS

Graduation exercises were held recently at the School of Aviation Medicine in Texas for another class of aviation medical examiners. The didactic portion of this course was conducted in Texas and the practical portion at three army air forces classification centers elsewhere. A list of graduates of this class follows:

ARKANSAS		CONNECTICUT	
Jack R. Ellis	1st Lieut. Hot Springs National Park	Harold W. Duennebier	1st Lieut. Hartford
David D. Fried	1st Lieut. Big Fort	Gershon B. Silver	Capt. Hartford
Robert H. Jack	on 1st Lieut. Little Rock	William E. Swift Jr.	1st Lieut. Hartford
Elmer J. Ritchie	Capt. North Little Rock	DISTRICT OF COLUMBIA	
Iett O. Scott	Capt. Hot Springs National Park	George J. Fleury Jr.	1st Lieut. Washington
George B. Talbot	Capt. Pine Bluff	Harold A. Timreck	1st Lieut. Washington
CALIFORNIA		Fred J. Wertz	1st Lieut. Arlington
Dor J. Hunter	1st Lieut. Bakersfield	FLORIDA	
Thomas M. Tullenlove	Capt. San Francisco	Julius Alexander	1st Lieut. Miami
Nicholas G. Maximov	Capt. San Francisco	GEORGIA	
Thomas A. Collins	1st Lieut. Fresno	Jack K. Bleich	Capt. Atlanta
Albert E. Fleming	1st Lieut. Fresno	James L. Campbell Jr.	Capt. Atlanta
Herbert W. Jenkins	1st Lieut. Palo Alto (Menlo Park)	Carroll E. McCarthy	1st Lieut. Columbus
George M. Plagens	1st Lieut. San Diego	John P. O'Brien	Major. Albany
Frederick J. Northway	1st Lieut. San Francisco	ILLINOIS	
		Edmund R. Adler	1st Lieut. Chicago
		George P. Ballard	Capt. Chicago

Arnold Black	1st Lieut. Chicago	Julius Levine	1st Lieut. Boston
Theodore R. Marquardt	1st Lieut. Lombard	Donald K. McCluskey	Captain Worcester
INDIANA		Charles C. Mister Jr.	1st Lieut. Boston
Earl K. Byrne	1st Lieut. New Albany	Francis A. Sullivan	1st Lieut. Danvers
Fred O. Clark	1st Lieut. Syracuse	MICHIGAN	
Raymond D. Miller	1st Lieut. Marshallville	Felix S. Alfemito	1st Lieut. Grand Rapids
Harold T. Moore	1st Lieut. Indianapolis	Bernard H. Fried	Capt. Detroit
James M. Pfeifer	1st Lieut. Lawrenceburg	Lyman E. Ihle	1st Lieut. Detroit

ARMY NEUROPSYCHIATRY SCHOOL OPENED

The War Department announced on January 2 that the first class at the Army's School of Military Neuropsychiatry began on January 4 at Lawson General Hospital Atlanta, Ga. The course will last four weeks. Only medical officers who have had a minimum of twelve months' full time training or practical experience in neurology or psychiatry will be eligible to attend. Each service command, the Office of the Surgeon General and the Army air forces will have quotas. Col William C. Porter Medical Corps, former chief of the neuropsychiatric division at Walter Reed Hospital, will be commandant of the school. He will have on his staff Major M. Ralph Kaufman, M. C. Major Joseph Fetterman M. C., and Capt William H. Exerts M. C.

FIELD TRAINING AT CARLISLE BARRACKS

Four hundred and eighty more officers of the Medical Department qualified for field duties on Dec. 30, 1942 when they graduated from the Medical Field Service School at Carlisle Barracks. They departed immediately for their respective units. All except four are experienced physicians, dentists, veterinarians or public health specialists. The officers' class composed chiefly of first lieutenants, who were recently commissioned after completing their internship and R. O. T. C. training were mostly Medical Corps officers. The subjects taught in this short intensive course included military art, military sanitation, logistics, field medicine and administration. The officers were from 43 states, the District of Columbia and Canada.

The number of Medical Department officers to be trained for field duty will be increased, starting this month. Three classes will be in session simultaneously, with one being graduated every two weeks.

In the class graduating on December 30 were 1 colonel, 2 lieutenant colonels, 8 majors, 133 captains and 224 first lieutenants of the Medical Corps, 1 lieutenant colonel, 1 major, 9 captains and 59 first lieutenants of the Dental Corps, and 2 majors, 3 captains and 24 first lieutenants of the Veterinary Corps, 2 captains and 5 first lieutenants of the Sanitary Corps, 1 first lieutenant of the Quartermaster Corps and 1 first lieutenant and 2 second lieutenants of the Medical Administrative Corps.

ARMY PERSONAL

Lieut. Col. James W. Howard has been assigned by Brig. Gen. Roy C. Hefebower, commanding general, Medical Replacement Training Center, Camp Berkeley, Texas, to be director of the operations and training division of the training center. Colonel Howard has been at the center since February 1942 in other capacities and has been in the Regular Army since 1933.

GRADUATE CLASS OF MEDICAL INSPECTORS

Forty-six officers in a class of medical inspectors received diplomas at graduation exercises at the Medical Field Service School at Carlisle Barracks, Pa., on December 31. Following the ceremonies the men left for their new posts. The duties of medical inspectors are to supervise sanitation and other medical preventive measures in army camps and to make recommendations for the correction of insanitary conditions. The class, composed entirely of Medical Corps officers, included four majors, forty-one captains and one first lieutenant. Another medical inspectors class of about fifty officers began in January.

ARMY AIDS NORTH AFRICAN NATIVES

The War Department announced on January 1 that when the American invasion fleet first landed in northern Africa it brought along hundreds of thousands of dollars' worth of tea, sugar and cotton cloth as barter goods in lieu of currency. Since then many shiploads of commodities have arrived, their distribution under the direction of the American high command helping to solve the labor problems and food supplies necessary to troop operations. North Africa needs commodities and above all medical supplies.

WAR MEDICINE MADE AVAILABLE TO BRITISH INSTITUTIONS

On recommendation of the Committee on Medical Research of the Office of Scientific Research and Development and with the collaboration of the American Medical Association the Josiah Macy Jr. Foundation is making the periodical *War Medicine* available to a group of British institutions selected by the liaison representative of the British Medical Research Council in Washington, D. C.

PROMOTIONS IN MEDICAL DEPARTMENT

Major Wayland R. Swanson, Post Hospital, Kearns, Utah, promoted to lieutenant colonel—Capt Robert I. Tenner, Billings General Hospital, Fort Benjamin Harrison, Indiana, promoted to major, and First Lieuts. I. Joseph Aprile, Donald Ross and John E. Burrett of the Billings General Hospital promoted to captains.

FLIGHT SURGEONS' ASSISTANTS

Another routine course of instruction qualifying enlisted men as flight surgeons' assistants began on Dec. 7, 1942 at the School of Aviation Medicine in Texas. The course will continue for six weeks.

NAVY

NAVY MEDICAL OFFICER AWARDED
SILVER STAR

The Navy Department announced on January 6, among decorations awarded to other navy medical personnel, the award of the Silver Star Medal to Lieut. John H. Peterson, M. C., U. S. N. R., of Springfield, Mass., for gallantry in the battle of Midway. Lieutenant Peterson's citation reads:

'For extraordinary gallantry and conspicuous intrepidity as Medical Officer of U. S. S. *Hammann* during and after action against enemy Japanese forces in the vicinity of Midway Island on June 6, 1942. Although he had been struck down and slightly injured by the shock of a torpedo explosion, Lieutenant Peterson, after abandonment of the sinking ship, persisted in manning a boat and directing the rescue of many seriously wounded men who might otherwise have drowned. For three days afterward he rendered constant medical attention to a great number of wounded and injured men aboard another destroyer en route to

its base until the strenuous exertion from his efforts weakened him to a point of complete physical exhaustion. His courageous initiative and tireless devotion to duty were in keeping with the highest traditions of the United States Naval Service.'

LAHEY CLINIC TRAINS SPECIALISTS
FOR ARMY AND NAVY

Almost since the beginning of the war the Lahey Clinic has been training anesthetists for the Navy and at present has a small group which will return to the service within a few days. The clinic is also training naval medical officers in roentgenology and navy corps men as laboratory and x-ray technicians.

The Lahey Clinic now has assigned to it also a small group of Army men for training in medicine, and shortly another small group will be assigned to the clinic for training in physical therapy. In addition the clinic is cooperating with the Massachusetts General Hospital in the training of thoracic surgeons.

CIVILIAN DEFENSE

BLOOD PLASMA RESERVES

The Office of Civilian Defense, Washington, D. C., issued Circular Medical Series No. 25 on December 21, which was as follows:

Plasma reserves are now available in every civilian defense region for use in the event of casualties resulting from enemy action or sabotage. The regional medical officer will keep all chiefs of Emergency Medical Service hospitals and Red Cross disaster relief chairmen informed concerning the amount and distribution of plasma reserves available in the state and how localities may secure additional supplies in emergencies. In cities where reserves are stored they may be obtained by hospitals through the local chief of Emergency Medical Services. If a community is without plasma or if its supplies are depleted, the local chief of Emergency Medical Service may obtain additional plasma in emergencies from the state chief of Emergency Medical Service. These instructions should not be construed to prevent the use of this plasma for life-saving purposes in any disaster. If Office of Civilian Defense plasma is used in non-war related incidents, its use may be considered as a loan, and arrangements may be made later for its replacement.

The Office of Civilian Defense, Washington, D. C., reported on December 29 that civilian reserves of blood plasma large enough to meet the requirements of more than thirty disasters as great as the recent Boston night club fire have been established at strategic locations throughout the country and are being added to constantly under the joint program of the Public Health Service and the Office of Civilian Defense.

As of December 1 there were 50,742 units of prepared plasma in its emergency reserves. Several thousand units have been added during the month, and the full quota of 133,130 units is expected to be reached within a few months. A unit is the

amount of plasma obtained from 500 cc. of blood and is sufficient for transfusion. The victims of the Boston fire required about 1,500 such units.

Although the reserves established under the blood plasma program of the Office of Civilian Defense are intended primarily for the protection of civilian casualties resulting from enemy action, they are available for saving lives in any disasters.

Liquid plasma reserves are maintained in more than a hundred and fifty hospitals which have received grants of federal funds for processing and storing plasma. Each of these hospitals maintains a reserve of at least 1 unit of plasma for each bed in the hospital. These will soon total at least 63,130 units.

In addition a number of hospitals which did not require grants for equipment are setting up plasma banks which will comprise an additional reserve of about 50,000 units for local authorities in case of emergency.

Frozen plasma has been obtained through the Army and Navy from blood collected by the Red Cross in excess of immediate service requirements. It is stored by the Office of Civilian Defense in refrigeration depots in important hospitals in the area if needed. A quota of 29,500 units of frozen plasma has been obtained for this purpose. Finally, 50,000 units of dried plasma is being stored in centrally located depots. Most of the plasma reserves are concentrated in the areas where enemy air raids are deemed most probable. Deposits are also maintained in inland regions.

In Boston at the time of the night club fire there were on hand in the city almost twice as many units as were required for treatment of victims of that disaster. More than 75 per cent of those hospitalized as the result of the fire required administration of some plasma. The superintendent of the Boston City Hospital estimated that it saved the lives of at least 75 persons who were treated there.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to *Curieux Marcellin* of Nov. 6, 1942, the German authorities have requisitioned the Beruyon, Lariboisiere and La Pitié hospitals in Paris, comprising 3,280 beds. Owing to the creation of temporary hospitals, Paris patients still dispose of 36,800 beds, which is little for a population estimated at 4,200,000. Since the beginning of war, no important epidemic has broken out with the exception of smallpox at the beginning of 1942, which was checked by intensive vaccination. Cases of scabies have increased from 1 to 70 per cent. Tuberculosis has doubled among 6 to 8 year old children and adolescents of 18 to 25. No general mortality figures have been published but the annual rate of deaths at the Cochin Hospital has increased from 1,200 to 1,400. People go to hospitals only in the last extremity because food cards must be deposited and inter-

minable formalities are required to get them back on leaving the hospital. British patients remaining in Paris are looked after at the Val de Grace and Jewish patients at the Rothschild foundation. All Paris hospitals suffer from enormous transport difficulties. There are hardly any ambulances. Patients are brought to the hospital with the help of the police first aid. For the return journey patients are grouped in the same ambulance, which makes a round trip like a motor bus.

Regegh Uysag Nov. 12, 1942 states that the health statistics of Budapest children are deplorable. Of 100,000 children 55,000 are suffering from nervous complaints—that is ten times as many as are suffering from consumption. It has been possible to reduce the number of cases of contagious disease, but the number of neurotic children has increased four-fold over the same period.

ORGANIZATION SECTION

TEXT OF THE OPINION AFFIRMING GUILT OF TWO MEDICAL SOCIETIES

DECISION WRITTEN BY JUSTICE ROBERTS

(From the Chicago Sun)

Washington, Jan 18—The text of Justice Owen J. Roberts' opinion in the Supreme Court's settlement of the antitrust act charges by the government against the American Medical Association and the Medical Society of the District of Columbia, both corporations, follows:

Petitioners have been indicted and convicted of conspiring to violate Section three of the Sherman Act, by restraining trade or commerce in the District of Columbia. They are respectively corporations of Illinois and of the District of Columbia. Joined with them as defendants were two unincorporated associations and 21 individuals, some of whom are officers or employees of one or other of the petitioners, the remainder being physicians practicing in the District of Columbia and members of the petitioners serving as to some of them, on various committees of the petitioners having to do with professional ethics and with the practice of medicine by petitioners' members.

CHARGES EXPLAINED

For the moment it is enough to say that the indictment charged a conspiracy to hinder and obstruct the operations of Group Health Association, Inc., a nonprofit corporation organized by government employees to provide medical care and hospitalization on a risk-sharing prepayment basis. Group Health employed physicians on a full-time salary basis and sought hospital facilities for the treatment of members and their families. This plan was contrary to the code of ethics of the petitioners. The indictment charges that, to prevent Group Health from carrying out its objects, the defendants conspired to coerce practicing physicians, members of the petitioners, from accepting employment under Group Health; to restrain practicing physicians, members of the petitioners, from consulting with Group Health's doctors who might desire to consult with them, and to restrain hospitals in and about the city of Washington from affording facilities for the care of patients of Group Health's physicians.

The District Court sustained a demurrer to the indictment on the grounds, among others, that neither the practice of medicine nor the business of Group Health is trade as the term is used in the Sherman Act. On appeal the Court of Appeals reversed, holding that the restraint of trade prohibited by the statute may extend both to medical practice and to the operations of Group Health.

CITES RECORD OF CASE

The case then went to trial in the District Court. Certain defendants were acquitted by direction of the judge. As to the others the case was submitted to the jury, which found the petitioners guilty and all the other defendants not guilty. From judgments of conviction the petitioners appealed to the Court of Appeals, which reiterated its ruling as to the applicability of Section 3 of the Sherman Act, considered alleged trial errors, and affirmed the judgments.

We granted certiorari limited to three questions which we thought important: 1. Whether the practice of medicine and the rendering of medical services as described in the indictment are "trade" under Section 3 of the Sherman Act. 2. Whether the indictment charged or the evidence proved "restraints of trade" under Section 3 of the Sherman Act. 3. Whether a dispute concerning terms and conditions of employment under the Clayton and Norris-La Guardia acts was involved and, if so, whether petitioners were interested therein and therefore immune from prosecution under the Sherman Act.

First. Much argument has been addressed to the question whether a physician's practice of his profession constitutes trade under Section 3 of the Sherman Act. In the light of what we shall say with respect to the charge laid in the indictment, we need not consider or decide this question.

GROUP HEALTH A BUSINESS

Group Health is a membership corporation engaged in business or trade. Its corporate activity is the consummation of the cooperative effort of its members to obtain for themselves and their families medical service and hospitalization on a risk-sharing prepayment basis. The corporation collects its funds from members. With these funds physicians are employed and hospitalization procured on behalf of members and their dependents. The fact that it is cooperative and procures service and facilities on behalf of its members only, does not remove its activities from the sphere of business.

If, as we hold, the indictment charges a single conspiracy to restrain and obstruct this business it charges a conspiracy in restraint of trade or commerce within the statute. As the Court of Appeals properly remarked, the calling or occupation of the individual physicians charged as defendants is immaterial if the purpose and effect of their conspiracy was such obstruction and restraint of the business of Group Health. The court said: "And, of course, the fact that defendants are physicians and medical organizations is of no significance, for Section 3 prohibits any person from imposing the proscribed restraints."

It is urged that this was said before this court decided *Apex Hosiery Co. v. Leader*, 310 U. S. 469. But nothing in that decision contradicts the proposition stated. Whether the conspiracy was aimed at restraining or destroying competition, or had as its purpose a restraint of the free availability of medical or hospital services in the market, the *Apex* case places it within the scope of the statute.

REFERS TO INDICTMENT

Second, This brings us to consider whether the indictment charged, or the evidence proved, such a conspiracy in restraint of trade. The allegations of the indictment are lengthy and detailed. After naming and describing the defendants and the Washington hospitals, it devotes many paragraphs to a recital of the plan adopted by Group Health and alleges that, principally for economic reasons, and because of fear of business competition, the defendants have opposed such projects.

The indictment then recites the size and importance of the petitioners, enumerates means by which they can prevent their members from serving Group Health plans, or consulting with physicians who work for Group Health and can prevent hospitals from affording facilities to Group Health's doctors.

In charging the conspiracy, the indictment described the organization and operation of Group Health and states that, from January, 1937, to the date of the indictment, the defendants, the Washington hospitals, and others cognizant of the premises facts, have combined and conspired together for the purpose of restraining trade in the District of Columbia.

In five paragraphs the pleading states the purposes of the conspiracy. The first is the purpose of restraining Group Health from doing business, the second, that of restraining members of Group Health from obtaining adequate medical care according to Group Health's plan, the third, that of restraining doctors serving Group Health in the pursuit of their calling, the fourth that of restraining doctors not on Group Health's staff from practicing in the District of Columbia in pursuance of their calling, and the fifth, that of restraining the Washington hospitals in the business of operating their hospitals.

REFERS TO HOSPITAL INFLUENCE

After reciting certain of the proceedings and plans adopted to forward the conspiracy, the indictment alleges that the conspiracy and the intended restraints which have resulted from it, have been effectuated in the following manner and by the following means and alleged that the defendants have combined and conspired with the plan and purpose to hinder and obstruct Group Health Association Inc., in procuring and retaining on its medical staff qualified doctors and to hinder and obstruct

the doctors serving on that staff from obtaining consultations with other doctors and specialists practicing in the District of Columbia. It states that, pursuant to this plan and purpose, the defendants have resorted to certain means to accomplish the end, and recounts them.

In another paragraph, the defendants are charged to have conspired with "the plan and purpose to hinder and obstruct Group Health Association, Inc., in obtaining access to hospital facilities for its members and to hinder and obstruct the doctors on the medical staff of Group Health from treating and operating on their patients in Washington hospitals." It is alleged that, pursuant to this plan and purpose, defendants have done certain acts to deter hospitals with which they were connected and over which they exercised influence, from affording hospital facilities to Group Health's doctors.

The petitioners' contention is, in effect, that the indictment charges five separate conspiracies defined by their separate and recited purposes, namely, conspiracy to obstruct the business of Group Health to obstruct its members from obtaining the benefit of its activities, to obstruct its doctors from serving it to obstruct other doctors in the practice of their calling and to restrain the business of Washington hospitals. The petitioners say that they were entitled to have the trial court rule upon the sufficiency in law of each of these charges and as this was not done the general verdict of guilty cannot stand.

CITIZENS APPEALS COURT ACTION

They urge that even though some of the named purposes relate to the business of Group Health, and that business be held trade within the meaning of the statute act, as the practice of medicine by doctors not employed by Group Health is not trade, and the operations of Washington hospitals are not trade, the last two purposes specified cannot constitute violations of section 3 and the jury should have been so instructed. In this view they insist that the jury may have convicted them of restraining physicians unconnected with Group Health, or of restraining hospitals, and, in so the verdict and judgment cannot stand.

If in fact the indictment charges a single conspiracy to obstruct and restrain the business of Group Health and if the recited purposes are really only subsidiary to that main purpose or aim or merely different steps toward the accomplishment of that single end, and if the cause was submitted to the jury on this theory these contentions fail.

When the case first went to the Court of Appeals that tribunal construed the indictment as charging but a single conspiracy. It said:

The charge, stated in condensed form is that the medical societies combined and conspired to prevent the successful operation of Group Health's plan, and the steps by which this was to be effectuated were as follows: (1) To impose restraints on physicians affiliated with Group Health by threat of expulsion or actual expulsion from the societies; (2) To deny them the essential professional contacts with other physicians, and (3) To use the coercive power of the societies to deprive them of hospital facilities for their patients.

AGREES WITH LOWER COURT

In the trial the District Court conformed its rulings to this decision and submitted the case to the jury on the theory that the indictment charged but one conspiracy.

We think the courts below correctly construed the indictment. It is true that in describing the conspiracy five purposes are stated which the conspiracy was intended to further, but in a later paragraph, still in the charging part of the instrument it is alleged that the purpose was to hinder and obstruct Group Health in various ways and by various coercive measures which are identical with the "purposes" before stated. The trial judge after calling the jury's attention to the juxtaposition of these two formulations of the charge added:

These purposes, it is alleged, were to be attained by certain coercive measures against the hospitals and doctors designed to interfere with employment of doctors by Group Health and use of the hospitals by members of its medical staff and their patients.

In immediate context the judge added:

"To sustain that charge the government must prove beyond a reasonable doubt that a conspiracy did in fact, exist to restrain trade in the district in at least one of the several ways alleged, and according to the particular purpose and plan set forth."

At another point the trial judge summarized the government's claim that the evidence in the case showed opposition by the petitioners to Group Health and its plan, that they feared competition between the plan and the organized physicians and that to obstruct and destroy such competition the petitioners conspired with certain officers and members and hospitals to prevent successful operation of Group Health's plan by imposing restraints upon physicians affiliated with Group Health by denying such physicians professional contact and consultation with other physicians, and by coercing the hospitals to deny facilities for the treatment of their patients.

QUOTIS LOWER COURT

Again the judge charged:

"Was there a conspiracy to restrain trade in one or more of the ways alleged? And again: If it be true that the District Society acting only to protect its organization, regulate its dealing among its members and maintain and advance the standards of medical practice, adopted reasonable rules and measures to those ends not calculated to restrain Group Health, there would be no guilt though the indirect effect may have been to cause some restraint against Group Health."

We need add but a word as to the sufficiency of the proof to sustain the charge. The petitioners in effect challenge the sufficiency in law of the indictment. They hardly suggest that if the pleading charges an offense there was no substantial evidence of the commission of the offense. But however the argument is viewed we agree with the courts below that the case was one for submission to a jury. No purpose would be served by detailed discussion of the proofs.

Third: We hold that the dispute between petitioners and their members, and Group Health and its members, was not one concerning terms and conditions of employment within the Clayton and the Norris-La Guardia Acts.

Section 20 of the Clayton Act as expanded by section 13 of the Norris-La Guardia Act is the only legislation which can have any bearing on the case. Section 20 applies to cases between "an employer and employees or between employers and employees or between employees or between persons employed and persons seeking employment involving or growing out of, a dispute concerning terms or conditions of employment" and provides that none of the acts specified in the section shall "be considered or held to be violations of any law of the United States."

DEFINES LABOR DISPUTE

Section 13 of the Norris-La Guardia Act defines a labor dispute as including "any controversy concerning terms or conditions of employment or concerning the association or representation of persons in negotiating, fixing, maintaining, changing or seeking to arrange terms or conditions of employment regardless of whether or not the disputants stand in the proximate relation of employer and employee."

It also provides that "a case shall be held to involve or to grow out of a labor dispute when the case involves persons who are engaged in the same industry, trade, craft or occupation or have direct or indirect interests therein or who are employees of the same employer or who are members of the same or an affiliated organization of employers or employees whether such dispute is (1) between one or more employers or associations of employers and one or more employees or associations of employees (2) between one or more employers or associations of employers and one or more employers or associations of employees or (3) between one or more employees or associations of employees and one or more employees or associations of employees or when the case involves any conflicting or competing interests in a 'labor dispute' (as defined in this section) of 'persons participating or interested' therein (as defined in this section)."

Citing these provisions the petitioners insist that their dispute with Group Health was as to terms and conditions of employment of the doctors employed by Group Health since the District Medical Society objected to its members, or other

doctors, taking employment under Group Health on the terms offered by that corporation

They assert that section 20 of the Clayton Act, as expanded by section 13 of the Norris La Guardia Act, includes all persons and associations involved in a dispute over terms and conditions of employment who are engaged in the same industry, trade, craft, or occupation, or have direct or indirect interests within. And they rely upon our decisions in *New Negro Alliance vs. Sanitary Grocery Co.*, 303 U S 552, and *Drivers Union vs. Lake Valley Co.*, 311 U S 91 as bringing within the coverage of the acts a third party, even though that party be a corporation not in trade, and employers and employers associations even though they be only indirectly interested in the controversy. They insist that as the petitioners and Group Health, its members and doctors other doctors and the hospitals, were either directly or indirectly interested in a controversy which concerned the terms of employment of doctors by Group Health the case falls within the exemption of the statutes and they cannot be held criminally liable for a violation of the Sherman Act.

CITES PETITIONERS' PURPOSE

It seems plain enough that the Clayton and Norris La Guardia Acts were not intended to immunize such a dispute as is presented in this case. Nevertheless, it is not our province to define the purpose of Congress apart from what it has said in its enactments, and, if the petitioners' activities fall within the classes defined by the acts, we are bound to accord petitioners especially in a criminal case, the benefit of the legislative provisions.

We think however, that, upon analysis, it appears that petitioners' activities are not within the exemptions granted by the

statutes. Although the government asserts the contrary, we shall assume that the doctors having contracts with Group Health were employees of that corporation. The petitioners did not represent present or prospective employees. Their purpose was to prevent anyone from taking employment under Group Health. They were interested in the terms and conditions of the employment only in the sense that they desired wholly to prevent Group Health from functioning by having any employees. Their objection was to its methods of doing business. Obviously there was no dispute between Group Health and the doctors it employed or might employ in which petitioners were either directly or indirectly interested.

In truth the petitioners represented physicians who desired that they and all others should practice independently on a fee for service basis where whatever arrangement for payment each had was a matter that lay between him and his patient in each individual case of service or treatment. The petitioners were not an association of employees in any proper sense of the term. They were an association of individual practitioners, each exercising his calling as an independent unit. These independent physicians and the two petitioning associations which represent them were interested solely in preventing the operation of a business conducted in corporate form by Group Health.

In this aspect the case is very like *Columbia River Packers Association Inc. vs. Hinton*, 315 U S 143. What was there decided requires a holding that the petitioners' activities were not exempted by the Clayton and the Norris-La Guardia Acts from the operation of the Sherman Act.

The judgments are affirmed.

Mr. Justice Murphy and Mr. Justice Jackson took no part in the consideration of the decision of this case.

OFFICIAL NOTES

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Program of Meetings to Be Held in Chicago,
February 15 and 16

The Thirty-Ninth Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, February 15 and 16. The Federation of State Medical Boards of the United States will participate in the congress. The program follows:

MONDAY, FEBRUARY 15 10 A M

Report of the Council on Medical Education and Hospitals of the American Medical Association

RAY LYMAN WILBUR M D Stanford University Calif

Chairman of the Council on Medical Education and Hospitals

Education and the War

EDWARD C ELLIOTT LL D Washington D C

Chief Professional and Technical Employment and Training Division
War Manpower Commission

Premedical and Medical Education as Related to the United States Army

BRIGADIER GENERAL JOSEPH N DALTON, Washington D C

Assistant Chief of Staff for Personnel United States Army

Medical Education as Related to the Procurement and Assignment Service

HAROLD S DREHL M D Minneapolis

Member Directing Board Procurement and Assignment Service for
Physicians, Dentists and Veterinarians

Graduate Education and the War

DAVID C BALFOUR M D Rochester Minn

Director Mayo Foundation for Medical Education and Research
